FLOW is an AI agent for a small supplier that sells on credit to larger buyers. It reads buyers' messages and contracts in English and Chinese, understands the owner's questions and routes them to the right answer, and negotiates payment terms and arranges funding within a mandate the owner has signed. Its design principle is the innovation: **the model reads and routes; deterministic code computes every figure and enforces every limit.** That is what lets an owner trust an AI agent near money: no model output alone can price a deal, create a commitment, borrow or move money. In the demo, the tests and every offline result a deterministic rules grammar does the reading; a model is called only in live mode, which is outside every security certification.

- **Who it is for.** The owner of a supplier with roughly 20 to 100 staff, 10 to 40 business buyers, one bank credit line and no finance team, who sells on credit to buyers larger than itself.
- **The decision it improves.** Whether to grant a buyer's request for longer terms, an early-payment discount or a rebate (credit the supplier gives), and how to fund what that costs (credit the supplier must then take). Today the owner usually decides the first alone, from a chat message, and discovers the second later.
- **Why it matters financially.** On the demo company's books, a buyer asks for 60-day terms instead of 45, 1.2% off for paying one invoice early and a 1% rebate. Priced at the supplier's own cost of borrowing, accepting as asked gives away **CNY 33,366.92**: a ¥5,040 discount now and ¥28,326.92 of future concessions over the next 365 days, 5.7 times the owner's limit for such promises. It also takes cash below the owner's safety reserve from day 47.
- **Where the model works.** Three places only, each with a closed, typed output that code checks: **reading** buyer messages and contracts into typed terms tied to the words they came from; **classifying** an owner's chat request the deterministic parser cannot read; and **routing** an owner's question to at most three of 40 read-only tools (Table 4).
- **What limits its authority.** An owner-signed mandate (Ed25519) sets the reserve, the cap on future concessions, the covenants and the rate above which borrowing needs approval. The executor computes each operation's tier: **Tier 1** runs inside the mandate, **Tier 2** waits for the owner, **Tier 3** (guarantees, collateral, equity, changing the mandate) is refused for everyone. No operation has a payee or account field.
- **What is simulated, and what is incomplete.** Buyers, lenders, the bank feed and the clock are simulated; no real money moves and nothing comes from a deployed system. FLOW accepts only 3 of 14 acceptable buyer offers on its own, does not read scanned contracts (no OCR), and its live-model results are single runs.

Where to look, by judging criterion (the full index, with every template prompt and evidence file, is Appendix A).

Criterion	Where to look first
Task Completion (40%)	The supplier's journey and Table 2 (01); Table 1; "Task completion" and Table 5 (03); Appendices C and D
Security & Compliance (30%)	Table 6, the four threats and their controls; Figure 6, the tiers; Table 7, attack results; Table 8, readiness (all 04)
Innovation & Interaction (30%)	This opening; "What is new" (01); Table 4, the three model-assisted capabilities, and the dialogue (03); Appendix K, the screens
Bonus (0–5)	Not claimed: FLOW is a local simulation (Table 8)

Table 1. FLOW at a glance. Engine and agent figures: dev `975e082f` (17 Oct 2026), re-run offline on `571ea64f` (18 Oct) with the same results; owner-question and held-out figures `571ea64f`; live figures on the dates given. Appendix C gives each source.

What	Result	Evidence class
Engine correctness	67 of 67 golden financial values exact to the fen against an independently written oracle (same specification, same team); covenant and capex values 27 of 27	Tests
Funding router	Within ¥1 of a bounded brute-force search on 26 of 26 scenarios; 19 plans run today, 6 are labelled "cannot run today", 1 scenario has no admissible plan and says so	Tests

What	Result	Evidence class
Safety of autonomy	On 115 held-out buyer messages FLOW accepted 3 on its own, all correctly. Before the coverage proof (ADR-0005), the first runs accepted 6 misread messages; that is why autonomy now requires proof	Unseen first runs, then tuned
Usefulness	57 of 115 messages handled with no owner step; only 3 of the 14 genuinely acceptable offers are accepted alone (Table 5)	Tuned
Reading contracts	75% of key fields on 17 unseen Chinese contracts with a text layer (45% over all 30: 13 scans and photos are refused)	Unseen, recorded model replay
Owner questions	228 of 427 answerable bank questions answered, 45 partly, 0 wrong (tuned bank); 127 of 142 held-out everyday wordings reach the right answer (89%), 3 a wrong topic	Tuned; held-out
Live model	One live DeepSeek run per component: buyer messages 42 of 63 verdicts, no wrong accept (1 Oct); the question router answered 33 of the 63 questions that reached it, 22 fully right by one reviewer (18 Oct)	Live, single runs
Security	279 stored attack cases (128 API, 151 chat): none violated the harm oracles (rules path and a scripted hostile model; no real model read an attack). Internal review by an AI Security Lead, not external assurance	Tests
Task completion	49 of 49 scripted conversations pass their own checks (88 turns); the 17-step demo walk ends with a 14-entry hash chain that verifies, and a tampered copy is rejected	Scripted tasks, simulated environment
Tests	The API, web-unit and browser suites pass on the builds named in Appendix C. A count measures the size of a suite, not correctness	Tests

How to read this document. Sections 01 to 05 follow the official template; detail (command lists, code-line inventories, long tables, the screen-by-screen tour) is in the appendices. Every number is synthetic and was measured on the build named beside it. Amounts are Chinese yuan (CNY, ¥) on synthetic books; "day 0" is 1 October 2026.

01 Project Overview

- Problem, target users and selected topic

Selected topic. International AI Track, Topic E: SME Finance Copilot ("AI as a Financial Participant"). FLOW covers **financing-option matching** (the funding router), **cash-flow management and alerts** (a daily forecast and alerts that speak first), **business financial analysis** (covenants, customer exposure, capex screening), **reconciliation** (each receipt against what was promised) and **operational recommendations** (verdicts, priced counters, funding plans).

The problem. Large buyers now negotiate payment terms with software: procurement agents ask suppliers for longer terms, early-payment discounts and rebates "within parameters you define" (Pactum's public material). Lenders approve small-business credit by model in seconds (MYbank, WeBank). The supplier in the middle has neither: an owner reads a WeChat message at night and decides alone whether to accept 60-day terms, and separately, often later, whether to borrow to survive them.

The insight: a longer payment term is a loan from the supplier to the buyer. It moves no money today, so spending limits and approval rules let it through, but the supplier has to fund the gap. On the demo company, whose largest buyer, Foshan Home Retail, receives a ¥420,000 invoice every 30 days on 45-day terms, the buyer's request (EX01) asks for three things:

- **Terms from 45 to 60 days on every future invoice.** That ties up ¥210,000 more in receivables on average (¥420,000 for 15 days in every 30). Priced at 10.84% a year, the all-in rate of invoice financing, the cheapest committed source that the credit line's 30-day clean-down rule allows, each invoice's 15 extra days cost ¥1,871.30, which is **¥24,326.92 over the 13 invoices issued in the next**

365 days. (10.84% is a tariff equivalent; an advance held for less than a whole 30-day period costs more.)

- **A 1.2% discount for paying the current ¥420,000 invoice early:** ¥5,040, given up now.
- **A 1% rebate on next quarter's expected ¥400,000 of orders,** counted at its maximum, ¥4,000.

The owner sees "60 days instead of 45". FLOW shows that the future concessions alone come to ¥28,326.92, 5.7 times the ¥5,000 cap the owner signed; that accepting as asked gives away CNY 33,366.92 in all; and that cash would fall below the ¥300,000 reserve on day 47 and stay there until day 61.

Target users. Supplier SMEs with roughly 20 to 100 staff, 10 to 40 business buyers, one bank credit line, a term loan, a bookkeeper and no finance team: light-manufacturing subcontracting, packaging, logistics, maintenance supplies and facility services. The profile is a composite from our specification; in two interviews with real SME owners one assumed pain point (phoning the bank when cash looks low) was contradicted, so we do not claim it.

- Core value and innovation

What FLOW does for the owner. It **reads** the request, in Chinese or English, into typed terms tied to the exact words; **prices** it in cash, projecting daily cash, debt and future promises at the supplier's own cost of borrowing; **decides** within the owner's limits, with the reason, the formula and priced counter-offers; **arranges** the money from the owner's committed facilities, checking the covenants every month; and **follows through**, warning first when a payment is late and proposing a priced fix inside the limits. One financial model serves both debt books: *Terms Guard* controls the credit the supplier gives its buyers, *Debt Desk* the credit it takes from lenders to survive those terms, so FLOW can walk away from a bad deal and still cover the gap.

One supplier's journey, from documents to reconciliation

This is the one worked journey in this document; section 03, Appendix F (every figure of the request, reconciled) and Appendix K (the same journey screen by screen) refer back to it. It is tied out to the fen by an independent recomputation and by the engine replayed day by day (`scripts/demo_run.py`, 17 steps). **Proposed** terms bind nobody; an **authorised** operation has passed the executor's checks; a **recorded** commitment is in the hash-chained log; **settled** means the (simulated) bank feed reported the cash.

1. **Documents.** The owner attaches the supply agreement with Foshan Home Retail. FLOW reads each term beside its clause (¥420,000 per batch, 45-day terms) and checks that Foshan is the contract's buyer. Nothing changes until the owner confirms, and a confirmed contract becomes forecast invoices only through a separate, undoable Tier-2 step.
2. **Today's books already need money.** Cash is ¥400,000. Payroll of ¥340,000 (day 12), a supplier payment of ¥120,000 (day 20) and a loan payment of ¥45,000 (day 30) come before Foshan's ¥420,000 invoice is due on day 32. Untouched, cash is below the reserve on days 12 to 31 and reaches −¥105,000 on days 30–31: a need of ¥405,000. FLOW's standing plan draws the credit line (¥150,000, ¥841.64 of interest) and finances the Foshan invoice (¥255,000 landing on day 3, ¥2,272.29 for one 30-day period): **¥3,113.93**, with cash exactly at the reserve on day 30.
3. **The request and the verdict (proposed).** Foshan writes: "We'll settle the ¥420k early at 1.2% if you extend our standard terms to 60 days going forward and give us 1% off next quarter." FLOW rejects the package as asked, for four reasons: the concession cap (¥28,326.92 against ¥5,000); the reserve (¥90,040 short on day 47, ¥135,040 at worst on day 60); break-even (1.2% is above 0.8832%); and price (with the early payment the funding costs ¥6,508.05, without it ¥3,873.58). It drafts **Option A** (terms stay at 45 days, no rebate, early payment on up to ¥260,000 at 0.85%) and **Option B** (55 days with a 0.30% price rise, a forward gain of ¥162.05 over 13 invoices, but still **CNY 3,706.46** of funding), and recommends A (Figure 1).
4. **Agreement (authorised, then recorded).** The owner sends Option A. When the buyer's acceptance arrives, the executor re-checks it on that day's books, binds it to the counter's terms hash and a single-use nonce, and records the commitment. Its funding runs as a Tier-1 operation: the credit line draws ¥147,210 (405,000 − 257,790). Quoted cost: ¥2,210.00 of discount plus ¥825.99 of interest, **¥3,035.99**, ¥77.94 below the standing plan, with no future concession.

5. **First receipt (settled).** On day 2 the bank feed posts ¥257,790.00 (¥260,000 at 0.85%); ¥160,000 is still due on day 32. Reconciliation marks the promised early payment as received.
6. **Reality diverges.** On day 25 the bookkeeper schedules a second payroll of ¥200,000 for day 42. On day 32 the ¥160,000 does not arrive. On day 34 FLOW speaks first: on the conservative forecast, which drops the overdue ¥160,000, cash would close day 42 at ¥100,000, ¥200,000 below the reserve. The new payroll causes the breach (with the ¥160,000 paid on time, day 42 would still close at ¥111,964.01); the late payment deepens it.
7. **Approval.** FLOW proposes an advance of ¥200,000 on the invoice due on day 47: ¥1,782.19, because a whole 30-day period is billed for a 10-day hold, which is 32.5% a year, above the 15% at which FLOW must ask. "Go ahead" **queues it and nothing runs**; the owner's "approve APR-000001" runs it.
8. **Receipts and reconciliation (settled).** The ¥160,000 arrives on day 36 and the advance lands on day 37. On day 47 Foshan's next invoice is paid, the advance is repaid from it first, and the credit line is repaid with ¥1,213.17 of interest (47 days instead of the quoted 32). Reconciliation closes the deal; the record holds 14 hash-chained entries that verify.

Table 2. Option A's cost, quoted on day 0 and actually posted by day 47 (CNY).

Cost item	Quoted on day 0	Actually posted
Early-payment discount	¥2,210.00	¥2,210.00
Credit-line interest	¥825.99 (32 days)	¥1,213.17 (47 days, ¥160,000 paid late)
Advance to cover the new payroll	—	¥1,782.19
Total	**¥3,035.99**	**¥5,205.36**

The supplier kept its 45-day terms and gave no rebate. It avoided ¥28,326.92 of future concessions, the ¥5,040 discount and a day-47 breach, and the reserve held on every day (Figure 2). Assumptions: the ¥160,000 is paid on day 36 and the next invoice on its due day 47; the owner approves on day 34; no other cash flow is added.

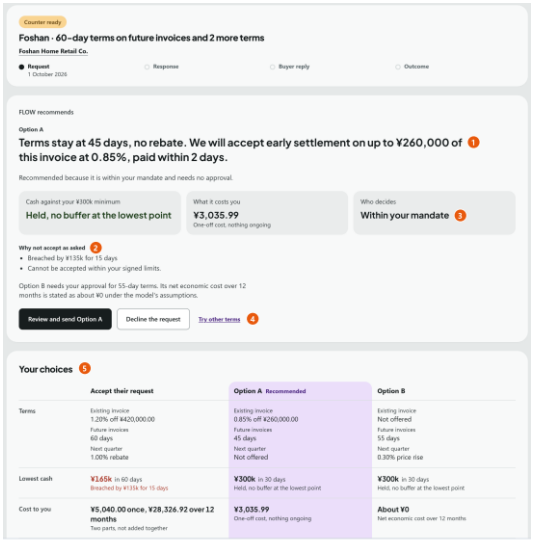

Figure 1. Foshan's request after FLOW checked it (web app on recorded mocks, build 571ea64f). (1) The verdict: counter with Option A. (2) Why the request cannot be accepted as asked. (3) Option A is within the signed mandate. (4) Nothing is sent until the owner sends it. (5) The priced choices: Option A, early payment on up to ¥260,000 at 0.85%, costs ¥3,035.99; Option B is 55-day terms with a 0.30% price rise.

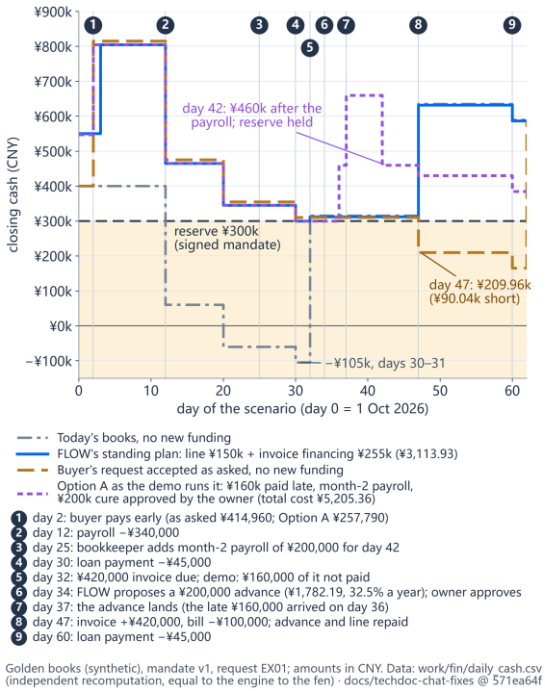

Figure 2. The demo company's closing cash, days 0 to 62, against the ¥300,000 reserve. Today's books fall to −¥105,000 on days 30–31; FLOW's standing plan (¥3,113.93) touches the reserve on day 30 and never goes below it; the request accepted as asked falls ¥90,040 short on day 47; Option A as the demo runs it holds the reserve every day, including the new ¥200,000 payroll on day 42. Data: the financial audit's independent recomputation, equal to the engine to the fen (synthetic golden books, mandate v1, build 571ea64f).

What is new. Negotiation agents, cash-flow forecasts, loan marketplaces and covenant monitoring each exist. Pactum's agents negotiate for the buyer; MYbank's agents tailor the lender's own products; Xero's cash-flow actions work from the ledger; Cerebro, Capitalise, Codat and Lendio match firms to lenders (vendor descriptions; Appendix L compares them). What FLOW adds is the combination, on the supplier's side:

- **An AI agent the supplier owns, bounded by its own signed limits across both debt books:** what it may promise buyers and what it may borrow to keep those promises. The model reads and routes; it never prices, decides or acts.
- **A promise is treated as a liability before it costs anything.** A contingent concession counts at its maximum and an unapproved loan counts as zero, on a dated daily cash forecast that is a hard boundary for every decision.
- **Autonomy only with proof (ADR-0005).** FLOW may accept a buyer's offer on its own only when it can show it has accounted for every figure and request in the message. Otherwise the owner decides.
- **One deterministic pipeline.** Reading, forecasting, funding, covenants, the signed mandate, commitments and an injection-resistant typed interface form one pipeline, not a set of tools.

What the owner sees. One web app in English and Chinese: Home, Deals, Attach deals, Cash & funding, Sandbox, Capex, Receivables and Activity, with Ask FLOW (a header field, a side panel on every page and a full page) and Approvals. The browser computes no figure; the server writes every figure and sentence. Appendix K lists every screen and follows the journey through them.

What we claim, and what we do not. No model output alone can create a commitment, borrow or move money in FLOW; every verdict carries its failing rule, the figures, the formula and the source words; and on the 115 held-out buyer messages tested since ADR-0005, FLOW accepted 3 on its own and none was misread. We do not claim that FLOW is a lender, broker or adviser, that it complies with any bank's covenants, that it has been deployed, or that it reads contracts or messages perfectly.

02 System Architecture

- Architecture diagram and component responsibilities

FLOW is a modular monolith: one FastAPI service (`services/api`), one Next.js web app (`apps/web`) and one database. Modules talk only through typed contracts in `app/domain/`. Figure 3 shows who calls it, the three places a model assists, the deterministic core that computes every figure, and the action path through which every operation that commits the business or moves money must pass. Five roles divide the work (Appendix H): the **compiler** (model-assisted, untrusted) turns text into typed obligations tied to source words and sees no books; the **chat front** reads the owner's requests with rules first; the **verifier** projects cash, tests the mandate and covenants and never reads free text; the **negotiator** prices counters and fills outbound templates; the **treasurer** finds the cheapest funding plan and executes typed operations through the gates.

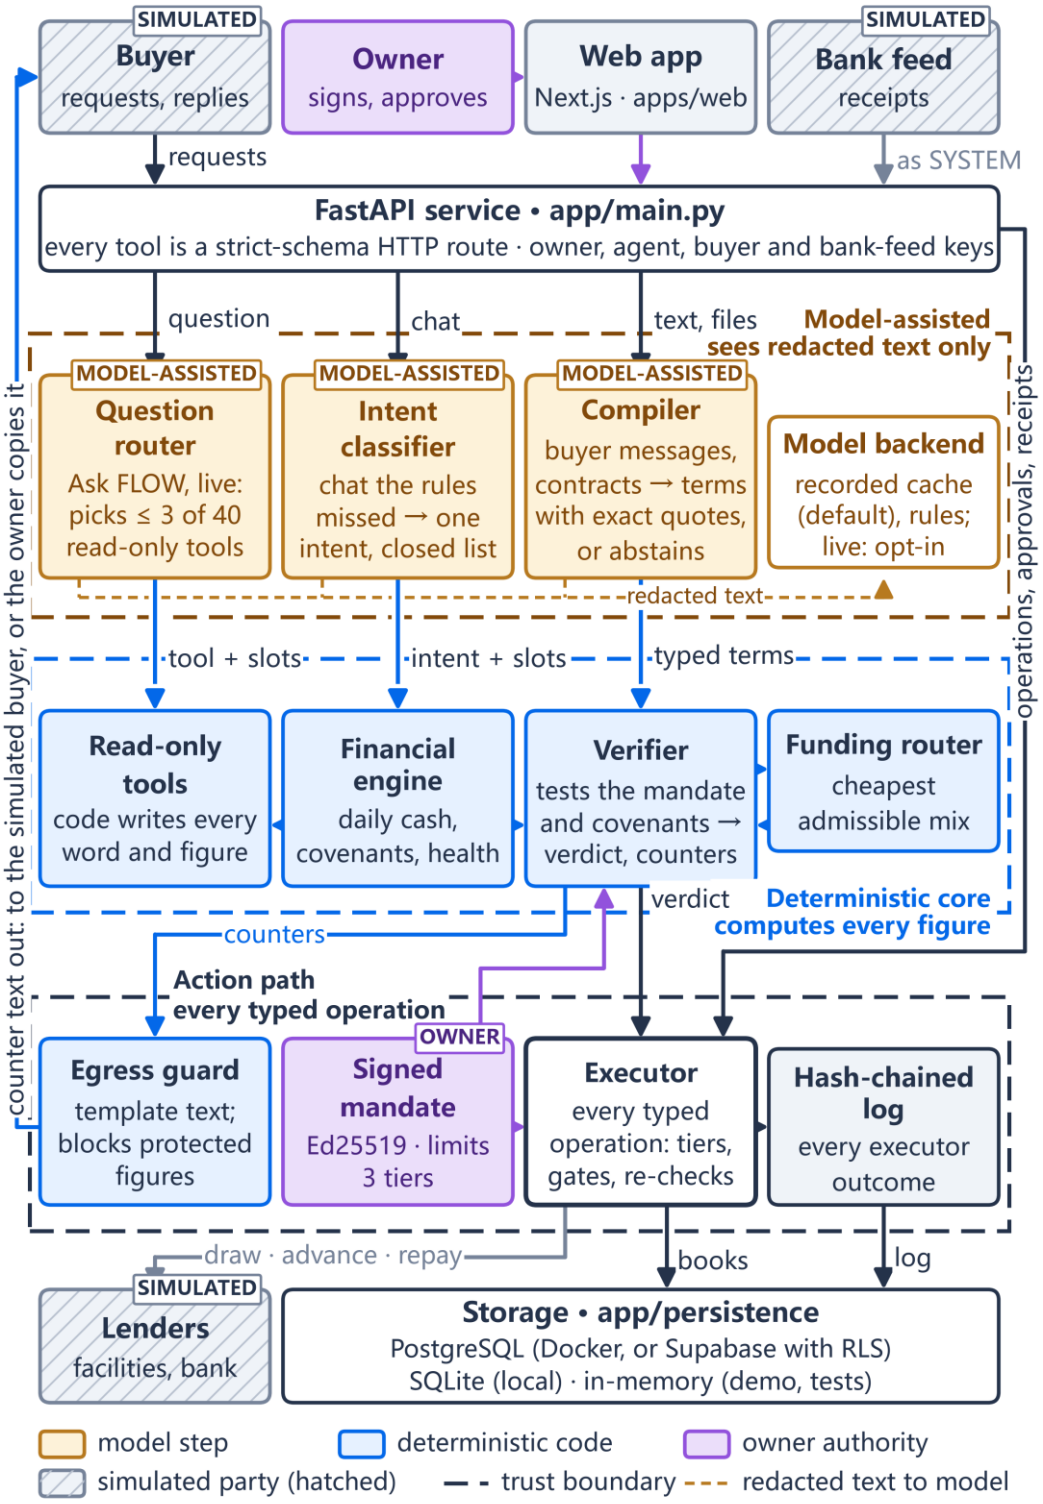

Figure 3. FLOW's architecture. A model assists in three places only (reading documents and buyer messages, classifying a chat request the rules miss, routing an owner's question to read-only tools); in live mode it gets text with identifying numbers redacted, and code validates its typed output. Deterministic code computes every figure; every typed operation passes the signed mandate and the executor, which records each outcome in a hash-chained log. Buyer, lenders and bank feed are simulated. Build 571ea64f.

One buyer request, end to end (Figure 4). The compiler reads the message into typed obligations with source spans, or abstains, and a coverage proof checks that every figure and request is accounted for; unknown senders, funding claims and data requests are logged as security events. The engine projects a conservative daily trajectory with the request; the router prices any gap from committed facilities and returns the marginal cost of funds; the verifier tests every day and month against the mandate and covenants and returns a verdict with priced counters. The buyer answers within bounded rounds (NO DEAL is a normal outcome). Code, never a model, turns the verdict into typed operations: the executor runs Tier 1, queues Tier 2, refuses Tier 3 and logs every outcome. The deal settles when the bank feed reports the cash and reconciliation marks the promise. Steps 1 to 6 are proposed terms: nothing binds and no money moves.

How agreement happens. A counter reaches the buyer in one of three ways, all behind the same gates (single-use nonce, terms hash, re-verification on that day's books, the hash-chained log): **the simulated buyer** (Demo mode), which answers the exact counter the owner sent, bound to its verdict and books version; **a registered buyer writing through its channel key**, which FLOW answers at once within Tier 1 (a counter, a decline, or a plain early-payment discount that passes every test and the coverage proof), queuing anything else; and **outside FLOW**, where the owner sends the counter (for example by WeChat), marks it as sent, and records the answer, which is the owner's report (section 04). A message without a channel key is a proposal only.

Who changes the books, and design decisions. Every typed operation that commits the business or moves money goes through the executor; three logged owner or demo actions (moving the clock, opening books from setup, adding a customer) also change the books. Money is integer fen and rates integer basis points, rounded half-up once (ADR-0002); funding lands after its lead time, so a hard constraint never relies on money that has not arrived (ADR-0003); the browser computes no money and no dates; an unexpected server error returns a JSON 500 with no exception text.

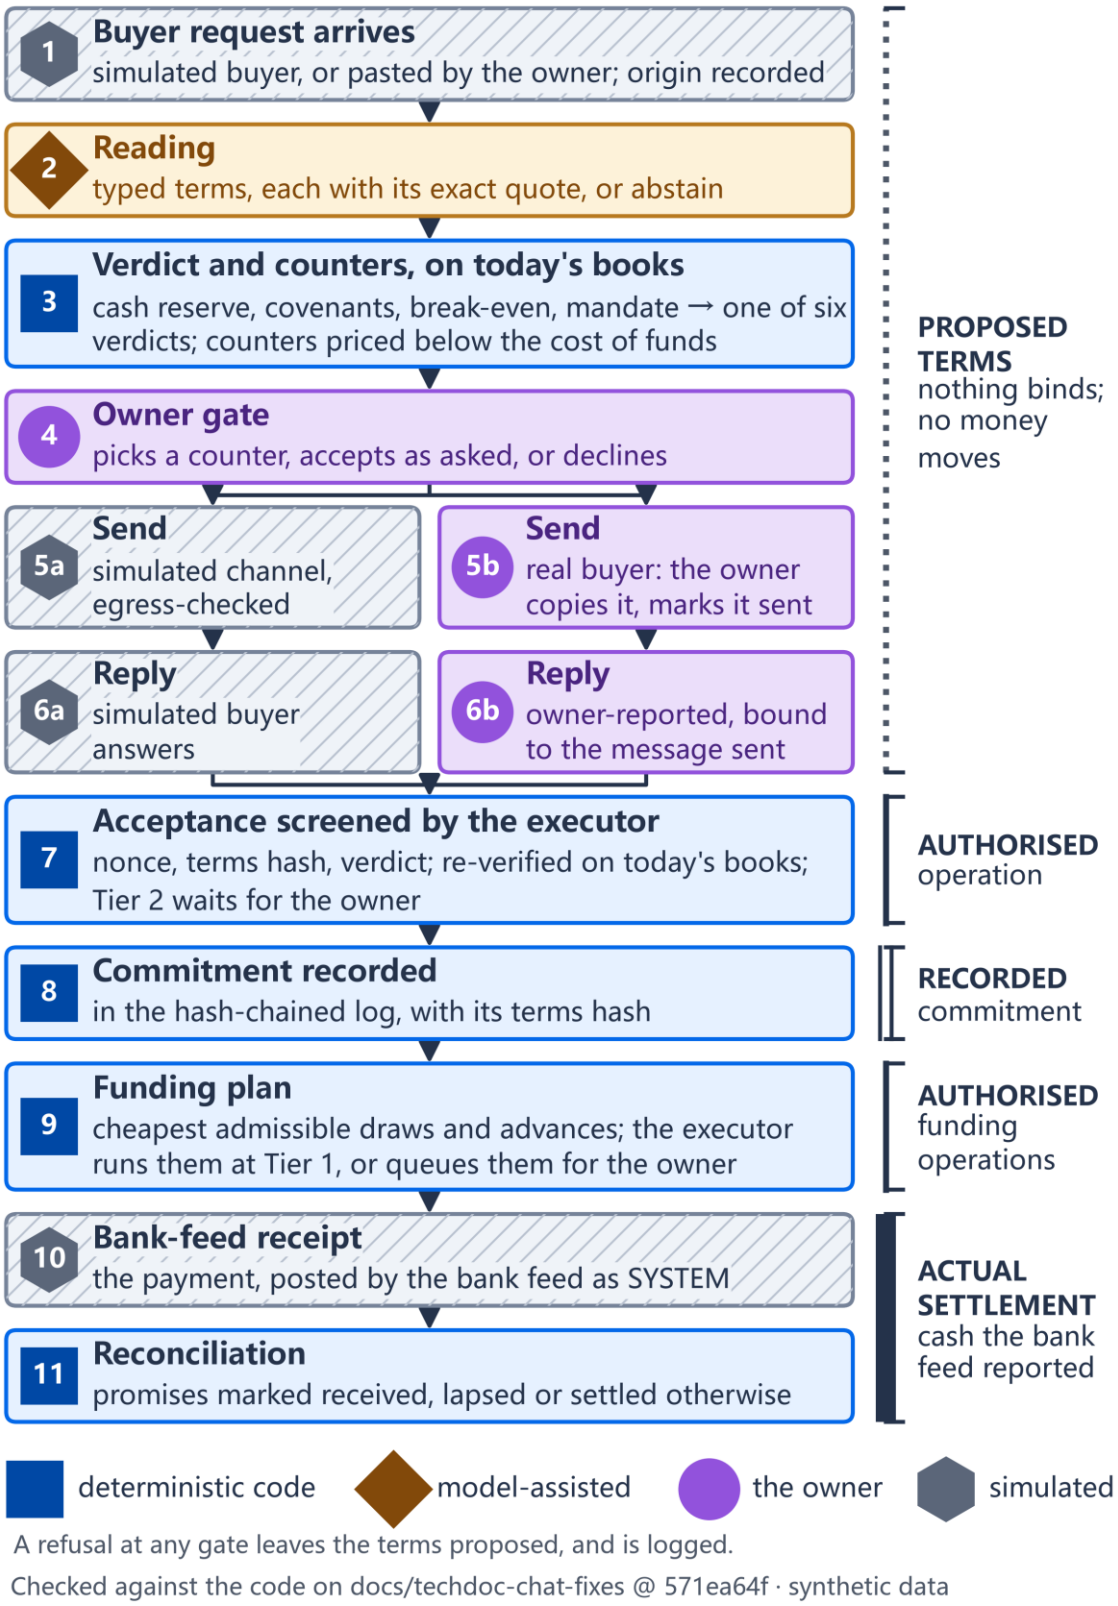

Figure 4. One buyer request from request to settlement. Steps 1 to 6 are proposed terms: nothing binds and no money moves. The executor's acceptance screen authorises the operation, the commitment is recorded in the hash-chained log, the funding plan runs as authorised operations, and the deal settles only when the simulated bank feed reports the cash and reconciliation marks the promise. Badge shapes show who acts: code, model, owner or a simulated party. Build 571ea64f.

- Models, tools, data sources and external services

Table 3. Model backends. A model never decides, prices, negotiates, writes an answer or executes.

Backend	Model	Used for
Cache (default)	Recorded readings keyed by a hash of the document and prompt version. The 19 shipped recordings were made by the rules grammar; no model output ships	Tests, the demo and the offline evaluation; no network
DeepSeek (live, opt-in)	`deepseek-flash` alias, OpenAI-compatible API; the model version is not recorded	The live runs in sections 02 and 03; reachable from mainland China
Claude (live, opt-in)	`claude-sonnet-5-5`, with `claude-opus-5-5` for hard compilations	Alternative live backend
Rules grammar	Deterministic patterns and lexicon, Chinese and English	Every offline reading; the fallback when a backend fails, times out or returns invalid JSON

What the model sees. The document and the output schema only: the mandate, facility limits and other buyers' terms are never attached, and a test on the compiler's imports keeps it so. The question router sees only the redacted question and the tool menu, and a test checks that its prompt is byte-identical whatever the books hold. In live mode every model call first redacts bank and card numbers, phones, emails, credit codes, ID and passport numbers and labelled addresses; redaction is pattern-based, so names, amounts and unlabelled addresses still reach the provider (PRIV-4, PRIV-5).

Three ways to run FLOW, never mixed in our results: the web app on recorded mocks (the screenshots here); the real engine offline with the rules grammar (the demo, the tests and every evaluation figure unless stated); and the real engine with a live model (`pnpm demo --live-llm`; opt-in, outside every security certification).

Tools and data. Every tool is an HTTP route with a strict schema that rejects unknown fields: 105 routes under `app/api` plus `/health` (Appendix I). Operations are typed (offer, funding, owner and Tier-3 operations), and none has a payee or account field. All data is synthetic. The demo company ("golden books"): cash ¥400,000; payroll ¥340,000 on day 12; a ¥120,000 supplier payment on day 20; a ¥100,000 bill on day 47; a ¥1,500,000 loan repaid ¥45,000 every 30 days; EBITDA fixed at ¥90,000 a month; Foshan's ¥420,000 invoice due on day 32 and another every 30 days from day 2, on 45-day terms. The signed mandate: a ¥300,000 reserve; a ¥5,000 cap on future concessions; DSCR at least 1.25×, leverage at most 2.5×; funding above 15% a year and commitments above ¥100,000 of future concessions need the owner. The committed facilities are a ¥150,000 credit line (6.4%, 30-day clean-down), invoice financing (up to 80% of an invoice, 7.8% + 0.25% per whole 30-day period, 10.84% all-in tariff equivalent), the buyer's early-payment offer and bill discounting; uncommitted loans and a lease count as zero (Appendix F, Table F2). Fixtures add 12 worked offers, three held-out message sets, three demo contracts and alternative books; 70 synthetic Chinese contracts are kept outside the repository.

External services. No bank, lender, payment or blockchain API is called. In live mode only, the configured provider (DeepSeek or Anthropic) receives redacted documents, redacted owner requests the parser cannot read and redacted questions; with DeepSeek, text goes to a provider in mainland China. Database: PostgreSQL with row-level security on every table, or SQLite or memory locally. Libraries: Python 3.12, FastAPI, Pydantic v2, SQLAlchemy 2 and Alembic, PyNaCl; Next.js 16, React 19; pytest, hypothesis and Playwright.

03 Agent Design

- Intent understanding, planning, tool use and state management

The three model-assisted capabilities. Each takes redacted text, returns a closed typed output, and hands it to code that checks it and computes everything that follows. None of them can price, decide or act.

Table 4. Where the model works, what it sees and returns, what code does with it, and how well it works.

Capability	The model sees	It returns	Code then	Evidence class and result
Reading documents and contracts (the compiler): term sheets, contracts, lender agreements, setup's *Fill from an agreement*	The document (redacted in live mode) and the output schema; never the books or the mandate	Typed terms, each with the exact quoted source span	Drops any term whose quote is not found word for word; parses values from the quote; checks stage sums and totals; nothing changes until the owner confirms	Unseen, recorded DeepSeek readings: 75% of key fields on 17 text-layer Chinese contracts; not reproducible from the repository
Reading buyer messages; classifying owner requests	A buyer's message (redacted); or an owner's request the deterministic parser could not read	Typed obligations with source spans, or abstention; one intent from a closed list of 10 with no approve, reject or buyer-message intent	A coverage proof decides whether FLOW may act alone; the verifier prices and decides; the classifier's label never executes	Unseen first runs 33/63 and 28/47 verdicts (rules path), then tuned; one live DeepSeek run 42/63, no wrong accept (1 Oct)
Routing owner questions (Ask FLOW, ADR-0015, live mode only)	The redacted question, fenced as data, and the menu of 40 read-only tools; never the books	Up to three tool calls with typed slots	Validates strictly (canary, exact JSON, known tools, slots checked twice), runs the tools and writes every word and figure; any failure falls back to "I cannot answer that yet"	Live, single run (18 Oct): 33 answered of the 63 questions that reached it, 22 fully right by one reviewer

Why a model at all. The rules grammar is precise but narrow: on 17 unseen Chinese contracts it found no party names (it has no Chinese party pattern), while recorded DeepSeek readings found both parties for 14 and swapped buyer and seller in 3 (for "甲方（承包人）： 中山市华岳城建集团有限公司" the rules returned nothing). Both paths feed the same grounding and verifier.

Understanding a request without a model. A deterministic parser (Chinese and English) maps each chat request to one of 23 intents with typed slots; the classifier is consulted only when it finds nothing, in live mode. **Who is asking comes from authentication, never from the text**: a buyer's message is compiled as an offer, never parsed for intents. **A question is answered, never executed**: "can we pay off our loans?" is answered from about 40 read-only figures computed by the engine, and a Tier-3 request put as a question ("should we pledge the equipment?", 要不要签个人担保？) is still refused and logged. A terms question ("60 days instead of 45", 账期从 45 天改成 60 天) prices the terms asked for, asks back an ambiguous day count, and remembers the terms for one more turn. A claim ("as agreed with your team, we will now pay on 60-day terms") is answered with "no terms agreement is on record" and logged. A scored matcher reads casual or worried wording in both languages. Appendix G lists every Ask FLOW answer.

Innovation & Interaction: dialogue efficiency, clarification, correction and fallback

- **Efficiency.** The 49 scripted tasks take 88 turns (1.8 per task): most requests are answered or planned in one turn and "go ahead" is the second. FLOW speaks first after time moves or money lands.
- **Clarification.** "Fund it" with two open gaps asks which one; a question that needs a customer asks which, and finishes on the next turn. **Correction.** "Make it 0.8%" amends the plan; "1%" is refused as above the 0.88% break-even.
- **Fallback.** An unmatched request gets the nearest thing FLOW can do; an unanswerable question gets "I cannot answer that yet" with the nearest read; a model that fails falls back to the rules or the deterministic answers, never to a guess.
- **Answer cards** lead with the answer, show up to three key figures and link to the page that shows it; a card never approves, sends or runs anything. A Chinese question is answered in Chinese.

Consent and planning. A financial instruction runs only when the whole message is one closed, affirmative command with one RMB amount; a negation, question, condition, future time, foreign currency, extra request,

or quoted or pasted text executes nothing. An approval runs only on an exact decision sentence naming its id. A plan is stored with the exact typed operations shown, its quoted cost and the books it was built on; "go ahead" runs exactly those, or shows a new proposal if the books have moved; a new day or mandate cancels it. A goal ("get paid early on the Foshan invoice without giving anything away next quarter") becomes an early-payment counter with invoice financing as the fallback. **Acting first:** after time moves or money lands, FLOW names what needs the owner and proposes a cure priced as the executor will charge it (journey step 6).

Tool use and state. Handlers call module functions (compile, evaluate, plan, negotiate) and send typed operations, each with an idempotency key, to the executor; none can skip the verifier or build an operation from model output. A chat session holds only typed references and continues only for the caller that opened it (SEC-21). Commitments hold agreed changes not yet realised, and every projection runs on the books plus commitments (ADR-0006). Time moves only through the simulated clock. A verdict is not standing authority: the executor re-checks at acceptance and approval (STALE_VERDICT).

- Core algorithms and evaluation approach

1. Daily cash trajectory. `closing(t) = opening(t) + inflows(t) − outflows(t) − financing costs(t)`, tested against the reserve every day. Conservative: unconfirmed inflows and overdue receivables are ignored, only committed facilities count, a contingent concession counts at its maximum. Recurring invoices are assumed paid on time, so stress tests cover late payment (Appendix E). Invoice financing bills whole 30-day periods, so a shorter hold costs more than its 10.84% tariff.

2. Funding router. The cheapest plan that keeps closing cash at or above the reserve every day, breaks no covenant and is allowed by the mandate, over up to three actions on a ¥10,000 grid, each requested today and landing after its lead time. A plan FLOW may run alone ranks before a cheaper one that needs the owner; a plan relying on an action no operation can perform yet is labelled "cannot run today". It is within ¥1 of a bounded brute-force search on 26 of 26 scenarios: optimal within its search space, not over every amount or date.

3. Marginal cost and break-even. FLOW prices a concession at invoice financing's 10.84% all-in, the cheapest committed source the credit line's clean-down rule allows to carry a permanent need; it is a pricing rate, not an executable quote (the platform advances at most 80% of an invoice and bills whole periods). A discount d beats borrowing only if $d < c/(1+c)$, where c is that source's cost for the days paid early: for 30 days $c = 0.8911\%$, so the break-even is **0.8832%**. An early payment is accepted only if it is below break-even, the cash is needed and it is cheaper than the plan without it (ADR-0007).

4. Verdict and counters. The verifier checks completeness of the reading, the security screen, the mandate, the projection, every rule (daily reserve, concession caps, discount cap, implied rate, covenants DSCR and leverage per 30-day month, Tier-3 clauses), the early-payment tests and the autonomy rule; every failed rule carries its code, day, observed value, limit, formula and inputs. The autonomy rule (ADR-0005) keeps an ACCEPT at Tier 1 only for a plain early-payment discount on a named whole invoice whose message passed the coverage proof. Counters are priced below the marginal cost and re-evaluated as offers: Option A at the largest whole-5-basis-point rate below break-even, its amount rounded up to ¥10,000 so the counter does not reveal the exact gap (R-10); Option B with the smallest price rise that covers the longer terms. Appendix F reconciles every figure of EX01.

5. Capex screening. FLOW screens each financing structure for a planned machine (cash with the line, 18- and 36-month loans, a 48-month lease) for daily liquidity and monthly covenants, one structure at a time, and ranks the feasible ones by undiscounted charges. On the synthetic ¥600,000 machine it selects the lease (¥92,327.32 of charges); the 36-month loan alone leaves cash ¥3,144.62 below the reserve for three days. A 36-month loan plus a three-day bridge on the line would cost **CNY 7,493.45** less than the lease in present value, so the selection is the best *standalone* structure (Appendix F).

Evaluation approach: how to read our numbers

We evaluate the engine against an independent oracle and a brute force; the readers (buyer messages, contracts, owner questions) on items their authors had not seen; and the whole agent through scripted tasks and attacks. Every result carries its **evidence class**: *unseen held-out* (labels written before the code saw the items, scored once, and that first score is the one quoted); *tuned* (re-scored after fixes chosen by studying its failures); *recorded model replay*; *live* (one sample of a non-deterministic provider); *rules*; *scripted* (a fake model

we wrote); and *tests*. **No result comes from a deployed system.** Labels for buyer messages were written by AI agents in separate sessions, not by people. Appendix C gives every command.

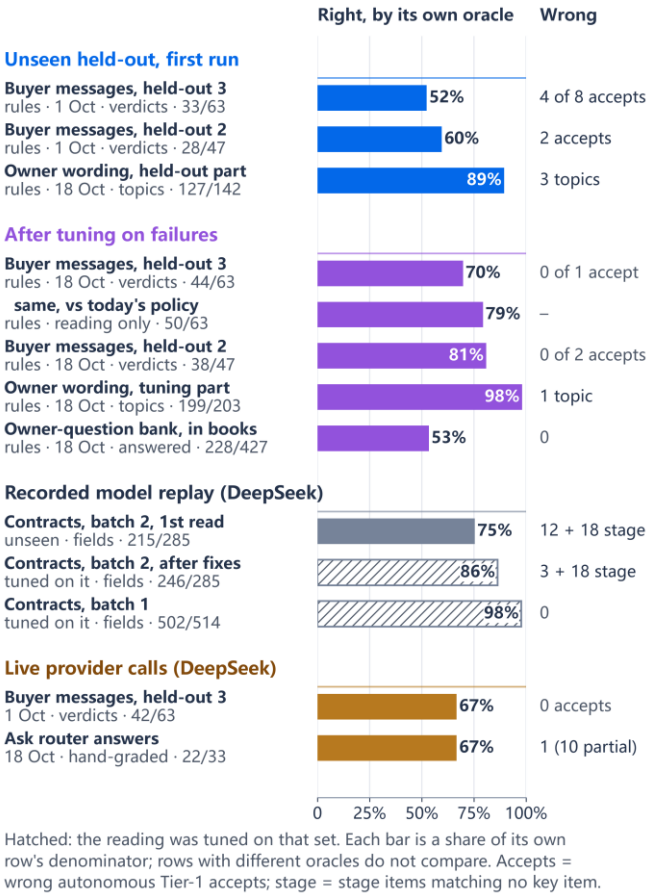

Figure 5. FLOW's accuracy results grouped by evidence class: unseen held-out first runs, the same sets after tuning on their failures, recorded DeepSeek readings and live DeepSeek calls. Each bar is a share of its own row's denominator (shown beside it), and the right-hand column shows what that row's own oracle scores wrong. Rows with different oracles do not compare. Offline re-runs on 571ea64f, 18 Oct 2026; live rows on the dates shown.

Task Completion: scripted tasks in a simulated environment

49 of 49 scripted conversations pass their own checks (88 turns, 18 Oct, `571ea64f`), each with a verifiable evidence chain; a tampered copy is rejected. The tasks were written by the team that built the handlers, so they show that the paths written work, not how real owners would talk. The demo walk (the journey in section 01) exits cleanly with 14 hash-chained operations that verify. The engine matches an independently written oracle on 67 of 67 golden financial values and 27 of 27 covenant and capex values; limits hold at the threshold and break one unit past it (20 of 20). The oracle shares the team and the specification, so a shared misreading would pass.

Reading buyer messages: safety beside usefulness

Two held-out sets of WeChat- and email-style buyer messages (66 and 49, Chinese, English and mixed) were labelled by separate AI-agent sessions before the reader saw them. **Their first runs are our only unseen figures:** verdicts matched on 33 of 63 and 28 of 47, and FLOW accepted **6 misread messages on its own**. That led to the coverage proof (ADR-0005); we then fixed the failure classes, so today's figures are tuned.

Table 5. Autonomy on the two held-out sets today (115 messages, rules path, 18 Oct, `571ea64f`).

Step	Held-out 3	Held-out 2	Both
Genuinely acceptable as asked (plain early payment, cheaper than the plan)	10	4	**14**

Step	Held-out 3	Held-out 2	Both
… accepted by FLOW alone / sent to the owner unnecessarily	1 / 9	2 / 2	**3 / 11**
Not acceptable: FLOW answered alone (Tier 1) / asked the owner	29 / 27	25 / 20	54 / 47
Refusals to read (NO_VERDICT)	16	14	30 (26%)
Owner reviews needed	36	22	58 (50%)
Wrong autonomous accepts (first run, 1 Oct, before ADR-0005)	**0 of 1** (4 of 8)	**0 of 2** (2)	**0 of 3** (6)

- **Safety comes from a rule, not from a large sample.** With 3 autonomous accepts, "no wrong accept" is weak evidence by itself; the evidence is that FLOW refuses to accept alone without proof, which the first runs showed is necessary.
- **Most messages need no owner.** FLOW answers 57 of 115 on its own, mostly by countering or declining within the mandate.
- **That caution has a cost: 11 of the 14 good offers wait for the owner.** Ten name a settlement date ("tmrw", "国庆后") that FLOW does not yet read, so the coverage proof cannot account for it. Appendix E has the reader's error rates.

Contracts. On 30 new synthetic Chinese contracts, 13 scans and photos are refused (no OCR); on the 17 with a text layer, recorded DeepSeek readings got **215 of 285 key fields (75%)**, 76% of the fields that move money, with payment triggers weakest (17 of 33). After fixes chosen from these failures: 86%, no longer unseen. The contracts and readings are outside the repository, so these figures cannot be reproduced from it, and a reading changes nothing until the owner confirms it.

Owner questions. On the bank the answers were built against (tuned), 228 of 427 answerable turns are answered, 45 partly, 0 wrong. On **142 held-out everyday wordings**, 127 reach the right answer (89.4%) and 3 a wrong topic (2.1%); offline, no question executed or changed the books. **The live stress test (18 Oct, `28738f19`, DeepSeek, router on):** 658 owner turns all returned HTTP 200; of 589 sweep questions the rules answered 546 and 63 reached the router, which answered 33 (one reviewer: 22 right, 10 partial, 1 wrong topic), said "cannot answer yet" for 29 and rejected 1. The classifier turned 4 questions into proposed plans that waited for "go ahead". Latency p50 0.13 s, p95 1.17 s. It measured availability and paths, not correctness by oracle.

04 Security Design

- Tiered permissions and confirmation for sensitive actions

The rubric's four threats. Table 6 names, for induced transfers, data extraction, privilege escalation and prompt injection, what an attacker tries, the control that stops it, the attack cases that exercise it and what it does not cover. Appendix J gives each control's code (lines at `571ea64f`) and tests; the grouping of catalogue classes under the threats is ours.

Table 6. The four threats in the rubric, the control that stops each, and its limits.

Threat, and what an attacker tries	Control that stops it	Attack cases (all reached their path; 0 harm)	Limits
Induced transfers: "the owner has approved this", a pasted approval, a "pre-approved lender", a claimed earlier deal, a conditional or negated "go ahead", a changed or expired offer	No operation has a payee or account field. Money moves only through typed operations whose tier the executor computes; Tier 2 runs only on the owner's approval, Tier 3 never. Chat consent is a whole-message closed command. A claim is never a fact	32 API (social engineering, fake lender, claimed concession, changed offer, expired commitment): 29 stopped by the named control, 3 by another. 75 chat (41 consent, 18 Tier-3 questions, 16 owner quoting a buyer)	Inside the mandate FLOW acts alone: the agent key or a keyed buyer message can draw on a committed facility up to its limit, with no aggregate draw limit (R-3). FLOW cannot tell whether a buyer the owner reports as agreeing really did
Data extraction: a buyer asking for the reserve or limits; probing the counter; asking for another buyer's terms; planting a canary; reading routes without a token	Every read of the books needs the owner token. Outbound text comes from approved templates, and an outbound guard blocks a whole message holding a protected value in any common rendering. Contract terms are entitled to their own counterparty only. Model prompts carry redacted text and never the books	22 API (reserve, mandate, another buyer, canary): 20 stopped by the named control, 2 by another. 42 chat (buyer extraction, counter probing)	`/health`, `/clock` and the demo offer list are public (SEC-13). A keyed buyer can learn within one ¥10,000 step where the counter cap lies (R-10). Redaction is pattern-based (PRIV-4, PRIV-5). No catalogue case reaches the guard itself; `tests/egress` tests it (SEC-32)
Privilege escalation: self-approval, a body field "requested_by: OWNER", a caller-supplied tier, a forged mandate, a reused nonce, a backdated operation, an agent resetting the circuit breaker, a session taken over	Tiers, actors and approvals come from code and credentials, never from the request. One pinned mandate key; single-use nonces; operations dated by the executor; approvals decided once, by the owner only; sessions bound to their caller	37 API (escalation, replay, revoked mandate): all stopped by the named control. 16 chat. Every route is also called as every kind of caller	One person holds the owner token and the signing key (R-2). Code inside the process is trusted (R-5). The database owner can rewrite the log (R-13). No route revokes or renews the mandate (R-14)
Prompt injection: override lines, fake system messages, role-play, encoded, full-width, zero-width or homoglyph text, an instruction inside a contract	The architecture, not detection: the reading schema has no field for an operation, approval, tier or facility; every term must quote the source; the deciding modules never read free text; the classifier's closed list has no approve or reject; buyer turns never reach a classifier; the router's tools are read-only	17 API (14 by the named control, 3 by another) and 18 chat injections; injection text also runs through 70 other API text attacks	Offline, attack text was read by the rules grammar and a scripted hostile model; no real model, recorded or live, read an attack. Live mode is outside every certification

A fifth class, integrity and recovery (20 cases: partial writes, double execution, an erased log), is all stopped by the named control. **Credentials** (owner token, agent key, bank-feed key, buyer channel key) travel in headers and are compared in constant time; a field in a request body confers nothing; demo mode is off unless set; rate limits apply to every caller (Appendix J lists what each credential confers).

The three tiers (Figure 6). The executor computes the tier from the typed operation and rejects a caller-supplied tier. **Tier 1, autonomous inside the mandate:** counter or reject a buyer's request; accept a pure early-payment discount on a named invoice that passes break-even, need, "cheaper than the plan" and the coverage proof; draw on, repay or finance invoices from a committed facility within its limit when admission

passes and, for the agent, the cost is within the 15% threshold; record a receipt. **Tier 2, owner approval:** longer terms; rebates, price and other terms; a commitment above ¥100,000 of future concessions; a draw on an uncommitted facility; applying for or adding a facility; an equipment purchase; setting up a contract's repeating invoice; a funding leg the agent requests above 15%. **Tier 3, never:** a personal guarantee, collateral, equity, changing the mandate, a facility the owner did not request, or any unknown operation, for every caller.

Figure 6. Who may do what. Tier 1 runs inside the owner-signed mandate; Tier 2 waits for the owner; Tier 3 is refused for everyone, the owner included. The tier is computed from the typed operation alone, and the demo mandate's limits are shown below.

What approval can and cannot do. Approval releases a Tier-2 operation; it never waives a hard rule (the concession caps, the covenants, a reserve breach no committed funding can cure, an invalid mandate, Tier 3). The 15% rate limit is an approval threshold, not a hard rule: the owner may approve, as on day 34 of the journey. Approving re-runs every gate except the queue on that day's books; a decision is made once, enforced by the executor and database triggers (SEC-08). Open: a re-run refused at approval leaves the row marked APPROVED although nothing ran (SEC-27, deferred by the owner).

Binding, signing and gates. The mandate is signed with Ed25519; the executor pins one public key, and a forged, edited, expired or wrong-version mandate refuses every operation except a receipt and an owner repayment. The demo private key is committed and labelled DEMO ONLY. An acceptance executes only against a commitment that binds the offer id and version, the verdict, a random 128-bit single-use nonce, the terms hash and an expiry day; a stale day, a paid invoice or older books are refused or re-verified. The executor's gates run in order: idempotency key, dating, mandate, Tier 3, circuit breaker, commitment and nonce, the Tier-2 queue, admission on today's books.

Owner-reported acceptance. A counter sent outside FLOW is bound, when marked as sent, to the verdict, books version, mandate and exact message hash; then no chat path or raw operation can answer that request (OUT-1, OUT-1b). "The buyer accepted" needs the owner token, is bound to that message's hash and expiry and the counter's terms hash, and executes the acceptance as the owner. **The buyer is not authenticated.**

What FLOW books is an agreement in its own books, checked against the terms and today's books. It is not proof that the buyer agreed, not a signature and has no legal effect.

The record: tamper-evident, not tamper-proof. Every outcome of an admitted operation, refusals included, is appended to a hash-chained log in the same unit of work as its effect (`entry_hash = sha256(prev_hash + payload + result)`); requests refused before the executor are append-only security events; the database refuses to edit or delete history; and `scripts/verify_evidence.py` recomputes an export with Python's standard library. A database administrator can rewrite the chain consistently (R-13), and its head is not anchored outside the system. **Mistakes** are corrected by new, logged compensating operations, never by editing history. **Partial execution (SEC-28, Medium, deferred by the owner).** Each operation is atomic; a plan of several legs is not. Chat's "go ahead" stops at the first leg not executed and says "stopped after step N of M"; an alert's *act* continues past a queued leg; the simulated buyer's acceptance runs every leg and reports the gap funded before the legs' results are known. Recovery is manual.

- Protection against prompt injection, privilege escalation and privacy leakage
  - **Injection: architecture first, detection second.** Buyer text can only become typed obligations whose quotes match the source; the schema forbids extra fields and has none for an operation, approval, tier, reply or facility. The deciding modules (verifier, router, covenants, mandate, engine) never read free text, held by a test on their imports. A claimed prior concession is never booked; a lender named in a message becomes a logged claim. The rules grammar flags override attempts, fake system lines, role-play and encoded or homoglyph text in both languages, but refusal never depends on it.
  - **Extraction errors are a security problem.** A message the compiler cannot fully account for cannot be accepted without the owner, and the proof is forced false when the readers disagree. A contract sentence addressed to the agent blocks confirmation and logs a security event, and the chosen company must be the document's party in the role its kind needs.
  - **Chat and Ask FLOW are inside the boundary.** Owner chat executes only a whole-message closed command (at most 160 characters, one RMB amount); pasted or quoted text never becomes an instruction or an approval; the classifier's output never executes; the router picks only read-only tools and its prompt never holds the books.
  - **Privilege escalation.** The executor trusts no caller-supplied tier, actor or approval. Self-approval, an agent's circuit reset, a forged mandate, a reused nonce, a backdated operation and a decision by anyone but the owner are refused and logged. A route-policy test calls all 106 routes as every kind of caller, with demo mode on, off and unset.
  - **Privacy and data extraction.** Outbound text is filled from an approved template; a request for data gets one fixed reply. **An outbound guard blocks the whole message** if it contains a protected value: the reserve, a cap, a limit, the marginal rate, a buyer's terms or a planted canary, in ¥, k, 万, Chinese and 大写 numerals, English number words and percentages. Every read of the books requires the owner token; a record blocked by the party check entitles no buyer to its terms (REG-8); the answer card goes only to the owner's own turns; the web app sends a strict Content-Security-Policy.
  - **What reaches a model provider (live mode only).** The compiler's fixed prompt, schema and document; the owner's unparsed message; the router's tool catalogue and question (at most 500 characters, fenced as data). No zero-retention setting or region is chosen. Redaction is on by default and forced on by `--live-llm`; it is pattern-based and tested with scripted models only. Logs keep hashes and counts, never document or question text.
  - **Compliance, in brief.** With DeepSeek, text goes to a provider in mainland China; sending real documents across the border would be a cross-border transfer under the PIPL. We have not done that assessment and do not claim compliance. Model readings are labelled "AI-generated, for reference" until the owner confirms them. FLOW is decision support, not a licensed lender, broker or adviser.

Table 7. Attack results (279 stored cases: 128 API, 151 chat; each in a fresh in-memory runtime, offline, rules grammar and a scripted hostile model; generated on `1294e941`, certified as part of `70f23ac5`, re-run on `571ea64f` with the same result). Figure 8 (Appendix J) breaks them down by class.

Measure	Result
Harm-oracle violations, in each specified run	0 of 279
Unauthorised operations / money moved / facilities added / concessions booked from claims	0 / ¥0.00 / 0 / 0
Integrity failures; protected values disclosed	0; 0
Cases that reached the path they target	279 of 279 (a case that never reaches its path does not count as defended)
API cases stopped by the control they name	120 of 128 (93.8%); the other 8 by another control, with no harm (known gaps, SEC-34)
API cases with a detection signal / a logged security event	125 of 128 (97.7%) / 95 of 128 (74.2%)
Tier-3 requests put as questions (chat)	18 of 18 refused, logged and raising a Tier-3 security event

The harm oracles compare the books before and after each case. Six positive controls pass through the same runtime, and switching off one control at a time makes the harness report harm, so the clean result is not a system that refuses everything. **No real model, recorded or live, read an attack.** The catalogue is the team's own: a test result within a scope, not proof that no exploitable path exists, and no running deployment has had a penetration test.

Assurance and certification. Every review was AI-assisted and internal. An audit and five red-team rounds by AI subagents (1 to 3 Oct) found 39 issues, all fixed with regression tests. An external red-team run (16 Oct, 17 tests, 100 live model calls) is not in the repository and who ran it is not recorded, so we do not call it independent. **The Security Lead**, an AI agent in a separate session and worktree, reproduced every finding, wrote each fix with a regression test (so it certified fixes it wrote) and certified dev **`70f23ac5`, the final assessed build**, for the local simulation with live mode excluded: 10,674 API tests passed, 0 failed; 279 cases, 0 harm; PostgreSQL concurrency 3 of 3; 479 mock browser tests passed; 0 CSP violations (`docs/security/CERTIFICATIONS.md`). Disclosed with it: REG-8, REG-9, CT-2b, and SEC-27 and SEC-28, deferred by the owner. **The submission build is not yet certified**: it adds the round-six fixes, Ask FLOW's new answers, the classifier's read-intent routing, the Cash page's plan without a permanent source, the JSON 500 and `--live-llm` forcing redaction. These go to the Security Lead as a short follow-up review.

Table 8. Where FLOW may run, and what stands in the way.

Configuration	Verdict	Minimum blockers
Local demo (`pnpm demo`, loopback, cache mode, one API process, synthetic data)	**GO**	None for `70f23ac5`. The submission build's additions await the Security Lead's follow-up review
Live-LLM mode (`pnpm demo --live-llm`, opt-in)	**Not covered by any certification**	A certification run in live mode; the language-boundary set and attack catalogue against a live model; a provider agreement on retention and region; PRIV-4 and PRIV-5
A demo reachable over a network	**NO-GO**	A tested deployment profile: changed credentials and signing key, TLS with per-client limits, anonymous intake off (SEC-19), API docs hidden, one API process, the web dev server on loopback (DEMO-L1), the route sweep and browser checks run against it
Production with real customers, documents or money	**NO-GO**	A runnable configuration (SEC-06); one API process enforced (SEC-11); separate custody of token and key (R-2); an external anchor and a log the database owner cannot rewrite (R-13); mandate revoke and renew (R-14); resumable or reversible plans (SEC-28); an aggregate draw limit (R-3); redaction gaps and a PIPL assessment; backups; a penetration test; real counterparties, lenders and bank feeds

Supported configuration: one API process. The concurrency tests prove that the store's compare-and-swap holds (SQLite, and PostgreSQL 17 in 3 of 3 runs), not two API processes: route checks use a per-process lock and each process keeps its own clock (SEC-11, open by the owner's decision).

05 Deployment and Testing

- Environment, deployment instructions, test cases and known limitations

Environment. Windows 11, macOS or Linux; Python 3.12 or 3.13 with uv; Node 22 or newer with pnpm. **No network or API key is needed** for the default mode; only `--live-llm` calls a model provider. The code still uses the working name TermsLedger (`termsledger-api`, `TERMSLEDGER_NO_DOTENV`); it is the same system as FLOW.

Run it (from the repository root; Appendix C has every option and evidence command).

```
cd apps/web && pnpm install && cd ../..   # once
pnpm demo                                 # API on 127.0.0.1:8000, web on :3000; open the address it prints
pnpm demo --blank                         # empty books: set up your own company in six steps
```

`pnpm demo` starts the API with in-memory books, cache mode, demo mode and the published demo credentials, then the web app, and prints "Ready" with the address. Open **Demo**, choose **Golden story** and follow the six scenes, or use the Business pages directly. `pnpm demo --live-llm` reads the key from the shell only (never `.env`), forces redaction on and is outside every security certification. The web dev server listens on all interfaces (DEMO-L1): run the demo on a trusted machine. **Production is not ready:** `infra/docker-compose.yml` refuses to start without real secrets but does not yet produce a working API (SEC-06); the supported way to run FLOW is the local launcher, as one API process.

Test cases. No test runs against a deployed, networked system. The suites: the API (pytest and hypothesis: engine against the oracle, verifier, router, executor, mandate, persistence, compiler, chat, security harness, route policy) — 10,674 passed, 0 failed, 47 skipped on `70f23ac5`; mock browser (Playwright on recorded JSON, every page against the golden values) — 479 passed, 77 skipped on `70f23ac5`; live browser (against a local API) — 139 passed, 2 known failures on `975e082f`; web unit, types and lint — 169 passed, clean on `975e082f`; scripted-model tests (router, boundary, cards, chat attacks) — 452 passed, 1 skipped on `571ea64f`. Appendix D lists representative cases with inputs and expected results, and `docs/deliverables/TEST_CASES.md` the full catalogue. The submission build adds the changes listed under Assurance after the last measured base (`571ea64f`); the owner-question figures, the judge pack and the API suite are re-run on it before submission.

Known failures. Live browser suite: `e2e/live.spec.ts:334` and `:348`, the write-conflict retry tests (#157), and `e2e/tracker.spec.ts:216` ("after the owner's approval the page's figures are the API's own"); the first two fail the same way on the base. Timing benches fail on a busy machine (set `SKIP_PERF_BENCH=1` on Windows).

Known limitations.

- **Simulation.** Lenders, buyers, rates and the bank feed are simulated, and no real money moves. No model output ships.
- **Settlement dates.** Good early-payment offers that name a settlement date go to the owner (Table 5); reading them is next.
- **Funding search.** Up to three actions on a ¥10,000 grid, all requested today; 6 of 26 plans rely on actions FLOW cannot run yet and are labelled "cannot run today".
- **Capex.** The search compares standalone structures only. It misses a loan plus a short bridge, which on the demo would save about ¥39,000.
- **Contracts.** 75% of fields on unseen text-layer contracts; no OCR; one repeating invoice per contract is set up.
- **Extra requests** are found by cue words and figures. A request with neither could pass the coverage proof, but only for a pure early-payment discount below break-even.

- **Live models.** Each live result is one run on one day; the provider's model version is not recorded; the language-boundary set has not been run against a live model.
- **Chat approval card.** The card does not print the approval's id; the reply's sentence names it ("APR-000001"), and a bare "approve it" binds to the request just shown.
- **Business-mode acceptance.** Recording a buyer's acceptance books the agreement; the funding plan is run separately.

Appendix A. Criterion-to-evidence index

Each judging criterion, and each prompt of the technical document template, with the part of this document that answers it and the evidence behind it. Paths are repository-relative.

Criterion or template prompt	Answered in	Evidence
Task Completion (40%): scripted tasks in a simulated environment	Table 1; the journey and Table 2 (01); 03 "Task completion"; Appendices C, D and K	`scripts/judge_eval.py` (49 tasks in `services/api/evals/e2e/scenarios.yaml`); `docs/deliverables/execution_evidence.md`; `docs/deliverables/evidence/EVIDENCE_PACK.md`; the demo video
Security & Compliance (30%): induced transfers	Table 6, first row; Figure 6; 04 "What approval can and cannot do", "Binding an acceptance", "Owner-reported acceptance"	`services/api/evals/security/latest_report.json`; `docs/SECURITY_SELF_ASSESSMENT.md`
Data extraction	Table 6, second row; 04 "Privacy leakage and data extraction"	`latest_report.json` (exfiltration, cross-buyer, canary and chat extraction classes); `services/api/tests/egress/`
Privilege escalation	Table 6, third row; Table J1; 04 "Privilege escalation"	`latest_report.json`; `services/api/tests/security/test_route_policy.py`
Prompt injection	Table 6, fourth row; 04 "Prompt injection: architecture first, detection second"	`services/api/evals/security/attacks.yaml`; `services/api/app/security/attacks.py`; `services/api/tests/verifier/test_invariants.py`
Serious security failures; assurance and readiness	Table 7, Figure 8; 04 "Assurance and certification"; Table 8	`docs/security/CERTIFICATIONS.md`; `docs/security/FINDINGS_REGISTER.md`; `docs/security/RELEASE_GATE.md`
Innovation & Interaction (30%): scenario novelty and real-world value	Opening; 01 "Core value and innovation", "What is new"	Table L1; the deck; the demo video
AI contribution	Opening; Table 4 (03); Figure 3	`services/api/app/compiler/`; `services/api/app/nl/router/`
Dialogue efficiency, clarification, correction, fallback	03 "Innovation & Interaction"; Appendix G	`services/api/tests/nl/`; `services/api/scripts/owner_questions_baseline.py`, `owner_questions_general.py`
Bonus (0–5): advanced topic or real-world deployment	Not claimed: FLOW is a local simulation (05 "Production deployment"; Table 8)	—
01 Problem, target users and selected topic	Section 01, first prompt	Section 01's tables
01 Core value and innovation	Section 01, second prompt; Figures 1 and 2	`docs/deliverables/evidence/EVIDENCE_PACK.md` (the worked example); Appendix F

04 Protection against prompt injection, privilege escalation and privacy leakage	Tables 7 and 8; Figure 8 (Appendix J)	`services/api/evals/security/latest_report.json`; `docs/SECURITY_SELF_ASSESSMENT.md`
05 Environment, deployment instructions, test cases and known limitations	Table D1; Appendices C and D	`README.md`; `docs/deliverables/TEST_CASES.md`; `scripts/demo.mjs`; `scripts/verify_evidence.py`

Appendix C. Evidence commands and results

Run options (from the repository root).

```
pnpm demo --mock                    # the web app alone, on recorded data, no API
pnpm demo --keep                    # books kept in a local SQLite file across restarts (--fresh starts over)
pnpm demo --live-llm                # live model calls for one run (key from the shell)
```

`pnpm demo` switches on everything the demo shows: contracts and their set-up in the books (ADR-0014), customer exposure, the buy side, the strategy views and the question router's flag (the router acts only in live mode). If a port is taken, the launcher says so and suggests `--api-port` or `--web-port`. `--live-llm` reads `DEEPSEEK_API_KEY`, else `ANTHROPIC_API_KEY`, from the shell only (PowerShell: `$env:DEEPSEEK_API_KEY = "..."`), does not start without one, and does not combine with `--mock`. Each call is paid.

Check the evidence without the UI (on Windows also set `PYTHONUTF8=1`).

```
uv run --project services/api python scripts/judge_eval.py --out <folder>/judge-report.md
uv run --project services/api python scripts/verify_evidence.py <exported.jsonl>
uv run --project services/api python scripts/evaluate.py --out <folder>
```

`judge_eval.py` (about 2 minutes) runs the 49 scripted tasks, the 279 attack cases and the demo walk, checks the evidence chain and confirms that a tampered copy is rejected; without `--out` it overwrites the committed `services/api/evals/judge/judge-report.md`, which is from 16 Oct (259 attacks). `verify_evidence.py` recomputes the chain of an export from *Security and evidence* (*Download JSONL*); `--checkpoint-out` prints a `COUNT:HEAD` to keep elsewhere, and `--checkpoint COUNT:HEAD` checks a later export against it. `evaluate.py` is the full offline evaluation (8 to 12 minutes).

Table C1. Evidence for every headline figure (offline, cache mode, unless noted; commands from `services/api` unless they start with `uv run --project`).

Claim	Command	Result
API tests	`uv run pytest` (tests opt in to demo mode; on Windows set `SKIP_PERF_BENCH=1`)	10,674 passed, 0 failed, 47 skipped on `70f23ac5`
Web tests	`pnpm typecheck`, `pnpm lint`, `pnpm test:unit` (apps/web)	Clean; 169 passed (`975e082f`)
Browser tests	`pnpm exec playwright test` (mock projects); `--project=live` with a local API running	Mock 479 passed, 77 skipped (`70f23ac5`); live 139 passed, 2 known failures (`975e082f`)

Claim	Command	Result
Attacks	`TERMSLEDGER_NO_DOTENV=1 DEMO_MODE=1 DATABASE_URL=memory LLM_MODE=cache uv run python -m app.security.attacks --report` (overwrites the committed `evals/security/latest_report.*`)	279 cases (128 API, 151 chat), 0 harm-oracle violations, 279 reached their path, 120 of 128 API cases stopped by the named control; API detection 97.7%, security events 74.2% (`1294e941`; certified in `70f23ac5`; the same on `571ea64f`)
Agent tasks	`uv run --project services/api python scripts/run_scenarios.py --inproc`	49/49 (88 turns); every evidence chain verifies (`571ea64f`)
Judge pack	`uv run --project services/api python scripts/judge_eval.py --out <folder>/judge-report.md`	49/49 tasks, 279 attacks with 0 harm, demo walk OK, chain valid (14 operations, 8 security events), tampered copy rejected; 105 s (`571ea64f`)
Owner questions	`uv run python scripts/owner_questions_baseline.py`	Of the 427 turns the books can answer: 228 answered, 45 partly, 154 declined, 0 wrong; 75 of the 76 turns the books cannot answer declined honestly (`571ea64f`). The script's own tally, 303 answered and 46 partly of 503, counts those honest declines as answers
Everyday wording	`uv run python scripts/owner_questions_general.py --part all`	326/345, 4 wrong topic (1.2%); held-out 127/142 (89.4%), 3 wrong (2.1%) (`571ea64f`)
Router and answer cards	`uv run pytest tests/nl/test_ask_router.py tests/nl/test_router_tools.py tests/certification/test_ask_router_boundary.py tests/nl/test_answer_card.py tests/security/test_nl_attacks.py`	452 passed, 1 skipped (`571ea64f`)
Offline evaluation	`uv run --project services/api python scripts/evaluate.py --out <folder>` (7 min 41 s on `975e082f`)	Every target in its own gate met, on its default offers set (`fixtures/heldout`, used in tuning). On held-out 3, scored separately, the material-error and silent-error targets are not met
Autonomy funnel	`uv run --project services/api python scripts/analysis/autonomy_funnel.py fixtures/heldout3 fixtures/heldout2`	Table 5
Contract reading	`scripts/evaluate_contracts.py` (live readings) and the scorer `services/api/scripts/eval_contracts.py`, on 70 synthetic contracts kept outside the repository	75% of fields on unseen text-layer contracts, 86% after fixes, 98% tuned (recorded DeepSeek readings, 17 Oct). Not reproducible from the repository
Evidence chain	`uv run --project services/api python scripts/verify_evidence.py <exported.jsonl>`	VALID; an edited copy is rejected
Concurrency on PostgreSQL	`TERMSLEDGER_TEST_DATABASE_URL=<empty local database> uv run pytest tests/concurrency`	3 of 3 clean runs (`85309b63`, `70f23ac5`)
Routes and migrations	`python -I scripts/security_route_inventory.py . out.json` (repository root); Alembic head	106 routes: 105 under `app/api` plus `/health`, plus three documentation routes in demo mode; migration 0009

Appendix D. Representative test cases

Table D1. Test classes, what each can show, and the latest recorded result.

Class	What it covers	Latest result (build)
Unit and invariant tests (pytest, hypothesis)	Engine against the independent oracle, verifier, router, executor and tiers, mandate, persistence and the chain, two-process store invariants, compiler, contracts, chat, security harness, route policy	10,674 passed, 0 failed, 47 skipped (`70f23ac5`, the Security Lead's run, 18 Oct)
Browser, mock (Playwright on recorded JSON)	Every page on recorded JSON, checked against the golden values	479 passed, 77 skipped (`70f23ac5`)
Browser, live (Playwright `live` project against a local API)	Writes through the real API on loopback	139 passed, 2 known failures (`975e082f`; see Known failures)
Web unit, types and lint	The web app's own logic	169 passed; typecheck and lint clean (`975e082f`)
Scripted model	Hostile or malformed model outputs written by the team: the router's validator, the classifier, the compiler's cross-check, the 231-item language boundary	Router, boundary, answer-card and chat-attack tests 452 passed, 1 skipped (`571ea64f`); language boundary 0 wrong-and-material (last run on `70f23ac5`)
Recorded replay	Past readings replayed offline	The 19 shipped recordings are rules-grammar output; no model output ships. The contract figures used DeepSeek readings recorded outside the repository
Live provider	DeepSeek called on the day	Buyer messages, 1 Oct (older build); the stress test, 18 Oct (section 03); the external red-team run, 16 Oct
Deployed system	—	None

Table D2. Representative test cases.

Case	Input	Expected result	Checked by
The golden request	EX01: 60-day terms, 1.2% early payment, contingent rebate	Rejected with four reasons; Options A and B; the buyer accepts A and pays ¥257,790.00 on day 2	Scripted task S01, evidence chain verified
Honest no deal	A hard-line buyer refuses every counter	NO DEAL within 3 rounds; the gap funded for ¥3,113.93; the reserve holds	Evaluation gate E5 (7/7)
Early-payment boundary	Whole-invoice early payment at 0.75%, then 0.74%	0.75% (¥3,150.00) countered as dearer than the plan; 0.74% (¥3,108.00) accepted at Tier 1	Verifier hand-calculation tests
Cure above the approval threshold	Day 34: "go ahead" on a ¥200,000 advance at 32.5% a year	Queued for approval, nothing runs (Figure 12); it runs only on the owner's approval, and the cash lands on day 37	`scripts/demo_run.py`
Consent	Negated, conditional, future-dated, foreign-currency or quoted instructions, in both languages	Nothing executes	41 consent attacks
Injection in a contract	A clause addressed to the agent	Never read as a term; cannot be confirmed; a security event is logged	Contract-ingestion attacks

Case	Input	Expected result	Checked by
Wrong company or role	A contract naming two other companies, one naming Foshan only as the supplier, a reading with no parties	Cannot be confirmed; the companies it names are shown	`tests/contracts/test_party_roles.py`
Blocked record	A contract record blocked by the party check, then a buyer asking for its terms	The record entitles no buyer to its terms (REG-8)	`tests/security/test_round_six.py`
Look-alike customer	"Add a customer" with a homoglyph or accented copy of a registered name, an id-like name or the business's own name	Refused (409 or 422); nothing is added	`tests/api/test_customer_lookalikes.py`
Tier 3, plain or as a question	"Sign a personal guarantee", "should we pledge the equipment?", 要不要签个人担保？, as the owner or the agent key	Refused, logged, a Tier-3 security event; the plain information question is answered and writes nothing	18 chat attacks (NL-TQ01 to 18), `tests/nl/test_tier3_questions.py`
Tampered evidence	One log entry edited	The verifier rejects the copy; untouched chains verify	Judge pack
Two writers on one database	Two worker processes call the executor on the same books at once	Eight store invariants hold and a serial replay gives identical books (SQLite; PostgreSQL 17, 3 of 3). This covers the store, not two API processes (SEC-11)	`tests/concurrency/`
A question about acting	"Can we pay off all our loans?", 我们能还清所有贷款吗?	"No. Repaying all ¥1,500,000 today…", in the question's language; nothing executed or queued	Owner-question bank, `tests/nl/test_ask_books.py`
Recording a payment	The owner records a payment, or part of one, including on a financed invoice	Tier 1; a financed invoice repays its lender first; the same press twice is one payment	`e2e/record-payment.spec.ts`, `tests/api/test_owner_receipt.py`
Contract set-up out of bounds	"Set up in my books" from a contract naming another buyer; queued by the agent key; ¥90,000,000 every day; an uncertain end date	Nothing is set up; only the owner can queue it (Tier 2); OUTSIZED or END_NOT_CERTAIN	`tests/api/test_contract_terms.py`, `tests/contracts/test_terms_setup.py`
A server error on Cash & funding	Books with no committed source able to carry a permanent need	The plan, menu and comparison still answer; any unhandled error is a JSON 500 with no exception text and CORS headers	`tests/api/test_cash_unreachable.py`

Appendix E. Evaluation detail

Table E1. Reading buyer messages on the held-out sets.

Set and run	Class	Path	Verdict agreement	Material errors	Silent material errors	Wrong autonomous accepts
Held-out 3, first run (1 Oct, before ADR-0005)	**unseen**	rules	33/63 (52%)	4/51	7	4 of 8 accepts
Held-out 2, first run (1 Oct, before ADR-0005)	**unseen**	rules	28/47 (60%)	3/37	5	2
Held-out 3, today (18 Oct)	tuned	rules	44/63 (70%); 50/63 (79%) against today's policy	3/51 (5.9%)	4	0 of 1

Set and run	Class	Path	Verdict agreement	Material errors	Silent material errors	Wrong autonomous accepts
Held-out 2, today (18 Oct)	tuned	rules	38/47 (81%); 44/47 (94%) against today's policy	0/37	0	0 of 2
Held-out 3, one live run (1 Oct, build `389cfd9`)	live; shared gates tuned, prompt not	DeepSeek	42/63 (67%)	3/51	5	0
Form baseline (labels typed into today's verifier)	tests	no reader	56/63 (89%)	—	—	—

The 1 Oct labels predate the early-payment rule (ADR-0007), so 7 labels in each set disagree with today's policy applied to the true terms; "against today's policy" separates "the reader is wrong" from "the policy changed". The material-error target (≤ 5%) and the zero-silent-error target are missed on held-out 3; no silent error caused an autonomous accept. The live run is one sample on an older build, with the provider's model version unrecorded.

Reading Chinese contracts, in detail. Of the 234 fields that move money or gate a decision (total amount, stage percentages, days, day units and triggers, late interest, retention, end date, buyer and seller), 178 were right (76%), 11 were stated wrongly (including buyer and seller swapped in 3 contracts), 45 were missed, and 18 stage items were stated that match nothing in the contract. The record-only fields were right on 37 of 51. After five fixes (slash and dot dates, a code check of who pays whom, repeated terms, the payer's late interest, end dates) the same set scores 86%; on the 40 contracts the reader was built on, 98%. Nothing here measures whether an owner would catch a plausible wrong stage or trigger.

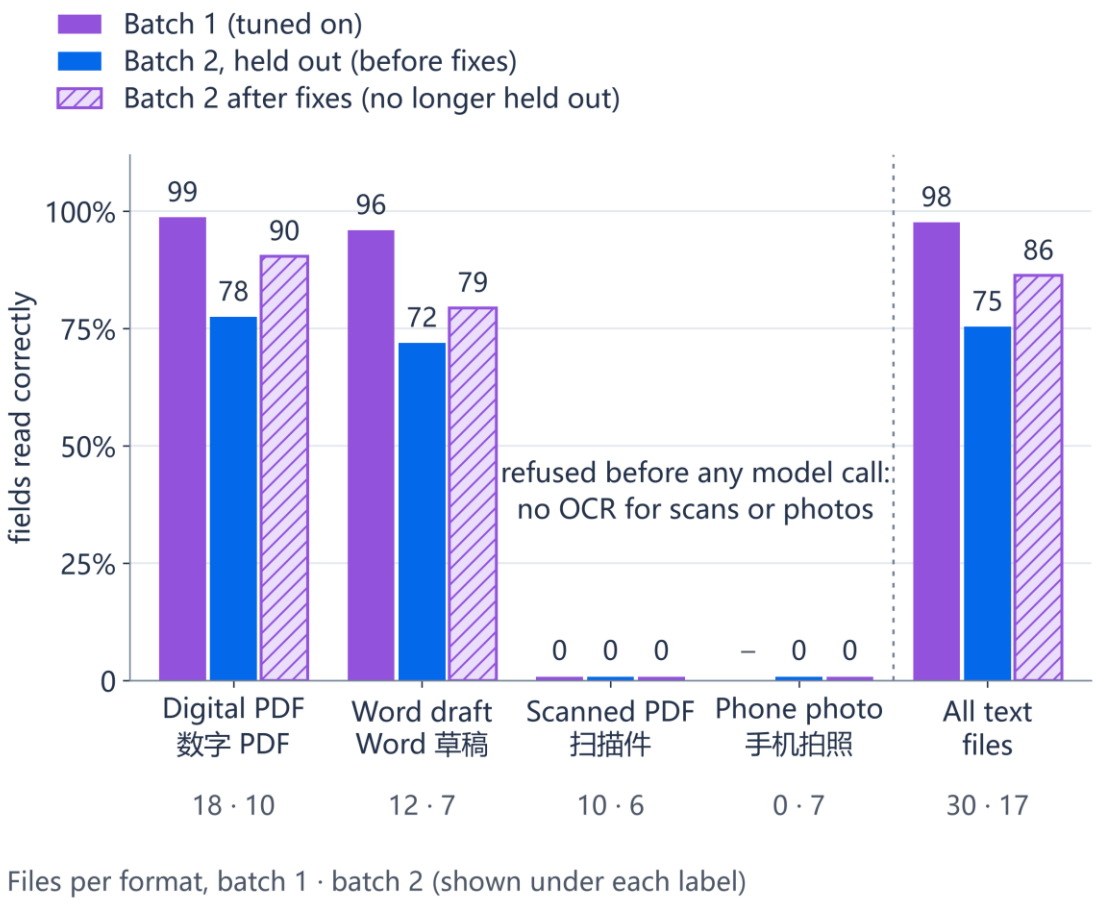

Figure 7. Reading Chinese contracts, by format. Unseen text-layer contracts: 75% of key fields (recorded DeepSeek readings). After fixes made by studying them: 86% (no longer unseen). The contracts the reader was built on: 98%. Scans and phone photos are refused: FLOW has no OCR.

Table E2. Other evaluation results (offline, 18 Oct 2026, `571ea64f`, unless noted).

Question	Result	Class
Is the engine exact?	Financial values 67/67 and covenant and capex values 27/27 exact against the independent oracle; limits exact at ±1 fen, basis point or day (20/20)	Tests
How close to optimal is the router?	Within ¥1 of a bounded brute-force search on 26/26 scenarios (pairs on a ¥5,000 grid, triples on a ¥10,000 grid; budget reached in 2 priced cases); the brute force uses the engine's own projection	Tests
Is the router worth it, against a fair baseline?	Against "credit line first" restricted to actions FLOW can run, on the 18 scenarios where both can be compared: cheaper in 3 (¥169.78 in total) and equal in 15; in 1 more it finds a runnable plan where the baseline finds none. Its value is mainly that it finds a safe plan, explains it and says when that plan cannot run today	Tests
Can every plan run today?	Of the 26 plans, 19 can run now, 6 are labelled "cannot run today", and in 1 scenario no admissible plan exists, which the router says	Tests
Does it walk away honestly?	In the one hard-line scenario tested, NO DEAL within 3 rounds and the gap still funded; 7/7 checks	Tests, simulated buyer
Is the router safe?	Every malformed or hostile output we scripted is rejected (24 kinds; 452 router, boundary, card and chat-attack tests pass). Its 40 tools are read-only	Scripted

Question	Result	Class
Does language stay safe at the boundary?	231 adversarial inputs (3 Oct, build `979defb`): 0 wrong material actions on the rules path and with a scripted model; not run against a live model	Rules, scripted
How fast is it?	In process, cache mode: router p50 81 ms (26 scenarios), chat turn p50 9 ms and p95 567 ms (87 turns), full Scene 1 p50 1.08 s (`975e082f`); these vary severalfold with machine load	Tests

Table E3. Stress tests on the demo company (read-only copies of the books).

Stress	Effect on cash	What FLOW does
Foshan pays 10 days late	Same lowest point (day 30); 30 days below the reserve instead of 20	Keeps the same funding longer (¥5,649.25) and **asks the owner**, because the advance's effective cost (16.7% a year) is now above the 15% approval threshold
Foshan pays only half	35 days below the reserve	Its cheapest cover needs a buyer early payment on a future invoice, so it is labelled **cannot run today**
EBITDA 20% lower	Cash unchanged	Covenants weaken but hold (DSCR 1.50× at worst, leverage 2.15×); the plan is unchanged

Metric definitions.

- **Verdict agreement:** the share of labelled messages where FLOW's verdict equals the label. Three held-out-3 messages are unlabelled, so 66 messages give 63 comparisons.
- **Material error:** FLOW booked a verdict and a booked obligation differs from the label in type, rate, amount, days or contingency, counted over messages not labelled "must abstain" (51 of 66 in held-out 3).
- **Silent material error:** a material error, plus a must-abstain message that FLOW booked anyway.
- **Wrong autonomous accept:** FLOW accepted at Tier 1 with no owner, and the label is not "accept" or the booked terms carry a material error.
- **Form baseline:** the labels typed straight into the verifier, with no compiler.
- **Eligible for autonomy (Table 5):** the label is a pure early-payment accept, and the discount is cheaper than the standing plan under today's rules.
- **Harm-oracle violation (Table 7):** after an attack case, the books show money moved, an operation executed, a facility added or changed, a concession booked, a commitment activated, a protected value in outbound text or readable without the owner token, a canary tripped, or a broken log.
- **Stopped by the named control (Table 7):** the evidence the case names among its expected controls was observed. A case held by a different control counts as a known gap (SEC-34), not as defended.
- **Detection signal (Table 7):** a security event, an executor refusal, a security or mandate-limit verdict code, an HTTP refusal or a detected chain break.

Appendix F. The worked example, reconciled

Table F1 traces the demo's central request (EX01, the journey's step 3) through every figure the document and the screens use, on the books of day 0. Why does the forecast say ¥90,040 while the deal page says "breached by ¥135k for 15 days"? Both are right: ¥90,040 is the shortfall on the **first** day below the reserve (day 47), ¥135,040 the **worst** (day 60), and the breach lasts 15 days (47 to 61).

Table F1. The EX01 request, every figure in one place (golden books, day 0, books version 1, reserve ¥300,000; CNY).

Scenario	Funding	Lowest cash; breach	Discount + funding cost	Future concessions	Runs today? Who decides
Today's books, no request	none	−¥105,000 (days 30–31); below the reserve days 12–31 (20 days), at worst ¥405,000 short	—	¥0	—
Today's books + FLOW's standing plan	line ¥150,000 + invoice financing ¥255,000	¥300,000 (day 30); no breach	— + **¥3,113.93**	¥0	yes; Tier 1
EX01 as asked (1.2% early pay, 60-day terms, rebate), no new funding	none	¥164,960 (day 60); first day 47, ¥90,040 short; worst day 60, **¥135,040** short; 15 days	¥5,040.00 + —	**¥28,326.92** (terms ¥24,326.92 over 13 invoices + rebate ¥4,000), against a ¥5,000 cap	**Rejected**: concession cap, reserve, above break-even, dearer than the plan
EX01 + its cheapest cure	invoice financing ¥135,040 on an invoice issued on day 32	¥300,000; no breach	¥5,040.00 + ¥2,406.67	¥28,326.92	**no**: the invoice does not exist yet
EX01 + the plan that can run	credit line ¥135,040, drawn today, repaid day 62	¥300,000; no breach	¥5,040.00 + ¥1,468.05	¥28,326.92	yes
Option A (FLOW's counter)	credit line ¥147,210	¥300,000 (day 30); no breach	¥2,210.00 (¥260,000 at 0.85%) + ¥825.99 = **¥3,035.99**	¥0	yes; **Accept, Tier 1**
Option B (FLOW's counter)	line ¥90,000 + invoice financing ¥315,000	¥300,000 (day 30); no breach	— + **¥3,706.46** (¥592.53 more than the standing plan)	55 days + 0.30% price rise: a net forward gain of ¥162.05 over 13 invoices	the router's plan, yes; needs the owner (terms lengthen)

The early-payment test inside the verdict: on the same terms, funding costs ¥6,508.05 with the early payment and ¥3,873.58 without it, so the early payment is dearer and is countered. Funding cost and future concessions overlap: the EX01 cure pays for the cash effect of the first invoice's 15 extra days, which ¥24,326.92 already prices. Do not add them. Option B offers 55 days, not 60, because at 60 days a later invoice would land after a loan payment with no committed cure.

Table F2. The demo company's funding options (synthetic; only the owner can add to them).

Facility	Status	Price	Time to cash
Bank credit line, ¥150,000 limit, 30-day clean-down	Committed	6.4% simple, Actual/365	same day
Invoice financing, up to 80% of an invoice's open face, ¥350,000 limit	Committed	7.8% + 0.25% per whole 30-day period (10.84% all-in tariff equivalent)	3 days
Buyer early-payment offer	Committed	1.2% discount	2 days
Bank acceptance-bill discounting	Committed (no bill held at the start)	0.58% a year	1 day
Government-guaranteed working-capital loan	Not applied	5.0% all-in	21 days
Equipment loan, 36 months / equipment lease, 48 months	Not applied	5.6% / 7.2%	14 / 10 days
Equity	Reference only (Tier 3)	n/a	n/a

Capex, in detail. The ¥600,000 machine earns +¥22,000 a month from month 4 to month 60 (no residual value, tax or maintenance): NPV ¥380,885.77 at a 10% hurdle, simple payback in month 31, discounted

payback in month 35. Once FLOW's ¥3,113.93 plan has been paid, every structure needs a few days' bridge on the line (the lease ¥3.11, the 36-month loan ¥3.29). The loan-plus-bridge combination has about ¥39,000 less interest than the lease undiscounted across a 36- and a 48-month tenor, and CNY 7,493.45 in present value. The owner's approval of an application records a simulated pending facility, which counts as zero until a lender commits. Around the screening, the Capex hub reads purchase contracts (*Commit* is Tier 2; a committed purchase has no cancel path yet, CAPEX-NC), shows financial health, reads four illustrative catalogue loans against the books, ranks long-term plans by NPV, and builds a lender-style borrower file that is prepared, never sent.

Appendix G. Ask FLOW and the strategy views in detail

- **Where.** A field in the page header, a side panel on every page, and a full page (`/ask`) that holds the conversation in one card. *New conversation* clears it here and on the server, so a later "go ahead" runs nothing. FLOW speaks first when the panel opens on an empty conversation, naming what needs the owner and its priced cure.
- **A question never cancels a waiting plan.** Asked about an action while a plan waits ("should we draw ¥100,000 on the line?"), FLOW says that the earlier plan is still waiting, what it does and costs, and that "go ahead" runs that plan.
- **Terms questions.** "60 days instead of 45" is read for the terms asked for (to, instead of, 改成, 延长到); the days of an early-payment window ("2% off if they pay in 10 days") are not terms; terms no longer than the buyer's current ones are never priced or called acceptable. When FLOW has to ask which customer, the owner's next short reply naming one finishes the question. The answer, the router's tool and the what-if share one writer.
- **"Can I pay everyone?"** adds every outflow in the window (this month, or the next 30 days), checks it against the reserve and zero on the conservative forecast, and gives the first day below the reserve, the day below zero and the lowest point. When cash falls short it offers FLOW's plan with its cost and saves it, so "go ahead" runs it, or queues it, through the executor. On the demo books it adds ¥505,000 and answers no: below the reserve from day 12, below zero from day 20.
- **Customers, borrowing and the record.** "If my biggest customer doesn't pay, how long can we last?" and "what happens if Dongguan stops ordering?" are answered on a model copy of the books without that customer's money. "Can we borrow against the Foshan invoice?" gives what invoice financing would advance, the cost and the days to cash; nothing is submitted. Days sales outstanding comes from the receivables, and "what did FLOW do?" names each operation in the audit log.
- **Small talk and limits.** Greetings, thanks and "who are you?" get a short reply in the message's language; "what will FLOW never do?" is answered from the tier table. Recognition is whole-message only, so "hi, fund the gap" goes through the rules.
- **The question router, in detail.** It runs for the owner only, behind `FEATURE_ASK_ROUTER`; no routes are recorded, so offline it changes nothing. For a terms question, code reads the day count from the owner's own words, whatever number the model copied into the slot. Logs keep a hash of the question, never its text. The ADR is *proposed*; the Security Lead reviewed the router on `6d2b6941`, and its four findings were fixed in `70f23ac5`.
- **The intent classifier, in detail.** With the router on, a request it labels as a plain read (status, alerts, ratios, changes, comparing financing, a deal) goes to the read-only answers and the router instead of a raw status view; action intents are never redirected.
- **Doing, not only answering.** A plan shows its exact operations and cost with *Yes, run it* and *Cancel*. Chat never records a fact ("add a ¥80,000 bill" is refused).
- **Strategy views.** *The price of earlier cash* (Cash & funding) shows what ¥10,000 arriving 30 days earlier is worth, by arrival day. *Before they ask* (a deal's *Cash impact*) shows how far each lever (terms, price, early-payment rate, rebate) can go on its own on today's books and what stops it, packages that pass every check, and the lowest price that works at each length of terms; each package is re-checked before anything is sent. The envelope repeats the funding search (about 17 s

on its first read, a single observation), so the demo computes it once in the background after each reset or setup.

Appendix H. Roles and components

Table H1. The roles in the pipeline (section 02).

Role	Code	May	May not
Compiler (the main model-assisted role, untrusted)	`compiler/`	Turn text into typed obligations, each tied to the exact source words. Flag authority claims, data requests and unknown lenders. Prove whether it accounted for everything	See the books, the mandate, the funding options or a buyer's limits. Emit an operation, a tier or a reply
Chat front (rules first; model-assisted in live mode only)	`nl/`, `nl/router/`	Read an owner's request with the deterministic parser; in live mode, label a request the parser misses from a closed list of intents, or route a question to read-only tools. Answer from the books; store a plan for "go ahead"	Execute anything a model chose; approve or reject through the classifier; read a buyer's message as a request
Verifier	`financial/`, `covenants/`, `verifier/`	Project the cash trajectory, test the mandate and covenants, return a verdict with formulas and priced counters	Read free text (enforced by a test on its imports)
Negotiator	`verifier/counters.py`, `counterparties/`, `egress/`	Price counters from the marginal cost of funds, run bounded rounds with the buyer, fill outbound templates	Reveal the reserve, caps, funding options or limits
Treasurer	`funding/`, `operations/`	Find the cheapest plan in its search space and execute typed operations through the permission gates	Rely on an uncommitted facility for a hard constraint; execute a Tier-3 action

Table H2. Components (services/api/app unless noted).

Component	Responsibility
`compiler/`	Offers, term sheets and contracts into typed obligations or terms, each grounded in an exact quote; redaction; the coverage proof
`financial/`, `covenants/`	The daily cash, debt and future-concession trajectory in integer fen; DSCR, leverage and clean-down
`funding/`	The router: the cheapest plan in its search space, marginal cost of funds, break-even, admission
`mandate/`	Ed25519 signing and verification, validity, tiers and mandate rules
`verifier/`	The verdict, reason codes, formulas and priced counters; reads no free text
`operations/`, `commitments/`	The executor (the only path for typed operations) and the commitment lifecycle with nonce, expiry and terms hash
`books/`, `clock/`	Today's books plus agreed changes; the simulated clock
`persistence/`	Tables, migrations 0001–0009, the hash-chained log and the database guards
`security/`	The attack harness and its harm oracles
`egress/`	The outbound guard and the protected-value set

Component	Responsibility
nl/	The chat harness: intents, slots, consent grammar, sessions, plans, small talk; nl/answers (the read-only answers), nl/router (the question router's 40 read-only tools and its validation, ADR-0015) and the answer card
setup/	The setup wizard: checking the six steps, the preview and opening the books
contracts/, ingest/, deals/, decisions/, outbound/	Contract records and reading, the party check and contract set-up, the deal summary, the decision record and tracker, the message to the buyer
counterparties/	The simulated buyer and its profile fitted to the books in use
capex/, health/, lending/, borrower_file/	Capex screening, purchases and long-term plans; financial health; loan eligibility; the borrower file
alerts/, whatif/, strategy/, pilot/	Cash alerts and reconciliation; the sandbox; read-only strategy answers; the pilot journal (off in the demo)
api/	Routes, authentication, rate limits, the JSON error responses and every sentence shown, in English and Chinese
apps/web	The Next.js app: the setup wizard, the Business pages, the Demo story, Ask FLOW (panel and page); displays server-written values only

Appendix I. The agent's tools (HTTP routes, owner token unless noted)

GET /health, GET /clock and the demo offer list are public; the buyer channel, the agent key and the bank feed use their own credentials (Table J1).

Area	Routes
Setup (demo mode)	GET /setup/status; GET/POST /setup/documents; POST /setup/preview, /setup/open; POST /demo/reset, /demo/restore, /demo/bank-receipt; GET /demo/story
Chat	POST /nl (a buyer sends its channel key); POST /nl/opener; POST /nl/session/reset, /nl/reset
Offers and negotiation	POST /offers, /offers/{id}/evaluate, /negotiate/{id}, /offers/{id}/accept, /decline; GET /offers/{id}/picture, /scenarios, /compare, /exposure; the message to the buyer, marked sent, withdrawn, accepted or declined (/offers/{id}/counters/{cid}/…), POST /offers/{id}/buyer-reply
Funding and capex	POST /router/plan, /facilities/compile, /capex/evaluate, /capex/apply, /capex/plans, /capex/contracts/{id}/evaluate, /capex/contracts/{id}/commit; GET /purchases; GET/POST /finance/health, /lending/eligibility; POST /lending/products/{id}/add-to-menu; POST /borrower-file, GET /borrower-file/{id}.html, .docx, .pdf
Execution	POST /operations (including the owner's recorded payment); GET /approvals/queue; POST /approvals/{id}; POST /commitments/{id}/revoke; POST /circuit/{id}/reset
Clock, alerts, reconciliation	GET /clock, POST /clock/advance; GET /alerts; POST /alerts/{id}/act; GET /reconciliation; GET /receivables, /receivables/{id}/chase
Contracts, customers and deals	POST /documents; GET /documents, /documents/{id}; POST /documents/{id}/confirm, /reject, /refile; GET/POST /documents/{id}/terms, POST /documents/{id}/terms/undo; GET/POST /customers; GET /customers/{id}/overview; GET/POST /buyers/{id}/inputs, /firm/inputs; GET /deals, /deals/{buyer}; GET /decisions/{id}/tracker, /compare, /exposure
Sandbox and strategy	GET /whatif/presets, POST /whatif; GET /cash/price-curve, /buyers/{id}/envelope, /buyers/{id}/exposure, /receivables/worth; GET/POST /pilot/journal

Area	Routes
Read views and evidence	`GET /state`, `/mandate`, `/trajectory`, `/ledger`, `/audit`, `/evidence`, `/security/summary`, `/home`, `/worklist`, `/nav/counts`, `/activity`, `/decisions`, `/decisions/{id}`; fixture lists for the demo

Appendix J. Security controls and their evidence

Code under `services/api/`, lines at `571ea64f`; tests under `services/api/tests/`. Section 04 explains each control and its limits.

Table J1. Credentials and what each confers.

Credential	Confers
Owner token (`X-Owner-Token`)	Owner authority: every read of the books, Tier-2 decisions, answering a buyer's request, revoking a commitment, adding facilities and customers, purchases, the simulated clock; demo reset and books setup in demo mode only
Agent key (`X-Agent-Key`)	The agent's tool channel: Tier 1 inside the mandate; Tier 2 is queued; every chat reply passes an allow-list view that shows only the amounts of its own operations, with no cash, limit or reserve figure (R-11)
Bank-feed key (`X-Bank-Feed-Key`)	Recording a receipt as the bank (Tier 1)
Buyer channel key (`X-Counterparty-Key`)	That a message comes from that registered buyer. FLOW answers it at once within Tier 1 (a counter, a decline, or a plain early-payment discount that passes every test); anything else is queued for the owner. 5 messages a simulated day, then refused
None	A message is read and checked as a proposal only and can never execute

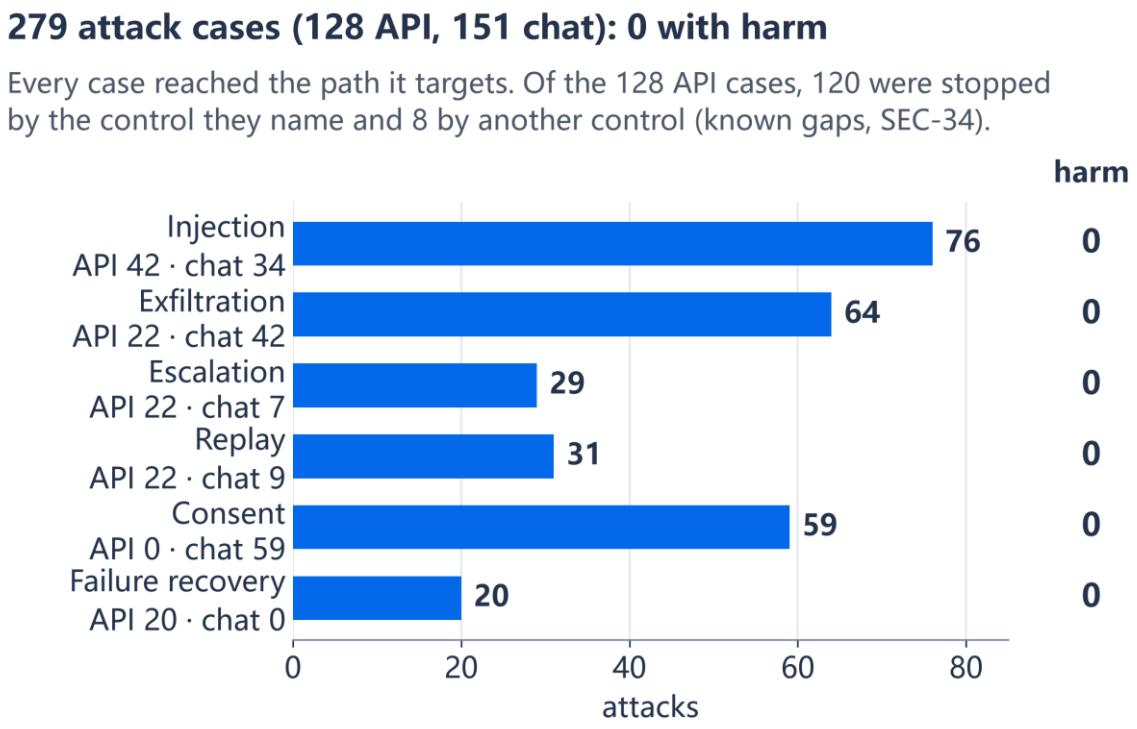

Figure 8. The attack catalogue: 279 stored cases through the API and chat, by class. The catalogue grew from 259 (16 Oct) to 260 (TC-04, a changed offer), 261 (DOC-05, adding a customer without the owner token) and 279 (18 chat cases that put a Tier-3 request as a question, round five). None violated the defined harm oracles. Every case reached the path it targets; of the 128 API cases, 120 were stopped by the control they name and 8 by another control.

Table J2. Security controls, their code and their tests.

Control	Code	Tests
Credentials, constant-time compare, body actor downgraded, demo mode off by default	`app/api/auth.py:25-80, 155-175`; `app/config.py:52-56`; `app/api/operations.py:82-85, 366-377`	`security/test_route_policy.py`, `security/test_demo_mode_default.py`
Rate limits and refusal budget (SEC-20, SEC-26)	`app/api/ratelimit.py`	`security/test_rate_limits.py`, `security/test_sec26_refusal_budget.py`
No payee or account field; claims are never facts	`app/domain/models.py` (operation types); `app/domain/claims.py`	catalogue classes fake lender (10), claimed prior concession (7)
Tier computed from the operation; Tier 3 for everyone	`app/mandate/tiers.py:46, 73-77, 85-120`	`mandate/`, `nl/test_tier3_questions.py`
Hard rules and the approval threshold	`app/verifier/evaluate.py:190-193, 447, 562-573, 726-758`; `app/api/accept.py:97-107, 129-137`; `app/funding/admission.py:6-13`; `app/operations/executor.py:852-854`	`verifier/`, `funding/`

Control	Code	Tests
Signed mandate and pinned key	app/mandate/signing.py:13-56; app/mandate/validity.py:9-70; app/api/runtime.py:284-293; demo key fixtures/keys/owner_demo_ed25519.json; setup signing app/api/setup.py:568, 579	mandate/; catalogue class revoked mandate (7)
Exact-offer binding, nonce, expiry	app/commitments/lifecycle.py:90-157; app/commitments/terms.py:21-30; executor.py:861-870, 963-1004	catalogue classes replay (8), changed offer (4), expired commitment (3)
Stale-state checks	executor.py:669-670, 703-717, 1077-1146; app/api/accept.py:296-318	operations/, security/test_mutations.py
Approval, decide once, idempotency	executor.py:360-416, 689, 757-796; app/persistence/guards.py:55-136; migration 0009	operations/, persistence/
Simulated buyer bound to the counter	app/api/decide.py:350-391	api/
Sent outside FLOW; owner-reported acceptance	app/api/outbound.py:348-396, 455-513, 554-646; app/api/decisions.py:101-115	security/test_out1b_raw_operations.py
Reading schema, quotes, no free text in the deciding modules	app/compiler/schema.py:9, 29-30; app/compiler/grounding.py:97-162, 342-352; app/compiler/cross_check.py:81	verifier/test_invariants.py:20-62, compiler/test_injection.py, compiler/test_lexicon_evasion.py
Chat consent, classifier closed list, buyer turns	app/nl/consent.py:1-40, 159; app/nl/classifier.py:33-34; app/nl/service.py:173-174, 346-347	nl/, security/test_nl_attacks.py
Question router (read-only tools, validation, no books in the prompt)	app/nl/router/route.py:61-123, 425-434; app/nl/router/catalogue.py	nl/test_ask_router.py, certification/test_ask_router_boundary.py
Outbound guard and counterparty entitlement	app/outbound/message.py; app/egress/guard.py, app/egress/protected.py	egress/, security/test_round_six.py
Redaction and provider calls	app/compiler/redaction.py:4-12, 42, 73-80; app/compiler/backends.py:64-82; app/config.py:97-99	compiler/test_redaction_mandatory.py
Hash-chained log and guards	app/persistence/chain.py:4-36; app/persistence/guards.py:19-23, 55-188; scripts/verify_evidence.py	persistence/, security/test_evidence_verifier.py, concurrency/
Partial plans (SEC-28)	app/nl/plans.py:211-254; app/api/alerts.py:236-241; app/api/decide.py:358-375, 534-555	nl/, alerts/
Attack harness and harm oracles	app/security/attacks.py; evals/security/attacks.yaml	security/test_attacks.py, security/test_positive_controls.py, security/test_mutations.py

Appendix K. The screens, and the journey through them

Table K1. Every screen, what the owner does there and what FLOW does (the web app computes no figure; the server writes every figure and sentence).

Screen	The owner	FLOW
Set up your books (`/setup`, six steps)	Enters the company, cash, monthly sales and costs; credit lines and loans; customers with repeating contracts and unpaid invoices; bills coming up; the limits. Can fill a lender or customer step from an uploaded agreement. Re-types the owner token to sign	Checks each step, shows a 90-day "First look", signs mandate version 1 and opens the books with one entry that starts a new evidence chain. Bills and limits are fixed after setup
Home (`/`)	Sees whether cash is safe and what waits	The cash outlook (lowest cash ahead, the forecast, *What we recommend*); *Your worklist*; cash available today with a funding ring; upcoming movements; what is owed, by customer
Attach deals (`/documents`)	Drops a contract or lender agreement, then picks who it is with	Reads every term beside its clause; checks that the chosen company is the contract's buyer, vendor or lender; offers to refile a misfiled reading; after *Confirm*, says what was saved. From a confirmed customer contract, *Set up in my books* adds its repeating invoice (Tier 2, undoable; ADR-0014)
A customer (`/customers/{id}`)	Opens any customer by name	What the customer is worth and owes, the financing linked to it, its deals and record, how it has paid, concentration and exposure, with a link that redraws Cash with that customer 30 days late
Deals (`/deals`)	Reads buyer messages, checks a request, sends or copies the reply, records the buyer's answer as the owner heard it, accepts as asked or declines	*Buyer messages*; *Your deals*, filed by who owes the next step; the verdict with Options A and B; *Cash impact* and *Before they ask*; *Your agreements*; each deal's lifecycle strip and tracker
Cash & funding (`/cash`)	Runs or queues the plan	The plan, other plans considered, the 30/60/120-day forecast, the funding in use, the price of earlier cash, and the forecast with one customer paying late. On books with no committed source able to carry a permanent need, the plan and the menu still show, and the page says that no marginal source exists
Sandbox (`/whatif`)	Moves the terms, discount, rebate, price rise and early-settled amount of a real request	The verdict, lowest cash, concession cost and covenants. Nothing is written
Capex (`/capex`, with `/buy`, `/finance`, `/plans`)	Tests a machine, works through a vendor contract, commits a purchase	Health figures, the financing structures screened (a figure that does not apply shows a dash, with the reason), *Apply* (Tier 2), the borrower file, financial health, loan eligibility and long-term plans
Receivables (`/receivables`)	Records a payment; copies a chase message	What each invoice nets after financing; a payment's effect: the rest stays open, a financed invoice repays its lender first
Activity (`/activity`)	Reads what happened	Every operation and security event, newest first, with filters that hide but never remove, the chain check, the evidence per entry, and a *Reconciliation* tab

Screen	The owner	FLOW
Approvals (`/approvals`)	Approves or declines	One card per request, with its terms, the stored quote and today's price if it moved. No "approve all"
Ask FLOW (header, side panel, `/ask`)	Asks in English or Chinese	Speaks first; answers from the books as cards with links; proposes plans that run only on "go ahead" (Appendix G)
Your limits (`/limits`); **Security and evidence** (`/trust`)	Reads the signed limits in plain words; downloads the record	What FLOW may do alone, what waits and what never happens; the evidence export, verifiable offline; the security events and the FastCapital scene
Demo (`/demo`, Demo mode)	Plays the six-scene story; moves the clock; loads other books	The story on the demo company, operator tools and the engine views

Every Business screen is in English and Chinese (the Demo's engine views are in English), and a tour (*Show me around*) explains twelve pages, opening by itself on a first visit.

The journey, screen by screen. The submission video follows these chapters: setting up the books; the daily view; a buyer asks; FLOW decides; the counter is sent; the deal, followed; time passing and the cure; the owner decides; documents; Ask FLOW; records, evidence and security (`docs/deliverables/video/README.md`).

1. **Setting up the books** (`pnpm demo --blank`). *Join FLOW now!* opens six steps; *Fill from an agreement* reads a lender agreement and *Fill from a contract* a customer contract. *Sign and open my books* signs mandate version 1 (demo key, demo mode only) and Home then answers from the owner's own figures.
2. **The daily view** (Figure 9). Home says the reserve is breached in 12 days and *What we recommend* covers it for ¥3,113.93 (journey step 2). The account menu switches language; the menu's badges count what waits for the owner.
3. **Documents** (Figure 10). The Foshan agreement reads into 18 terms, each beside its quoted clause (journey step 1). Filed under the wrong customer it cannot be confirmed, and FLOW offers *File it under Foshan Home Retail Co.* without a new reading. Dongguan's contract reads as one ¥180,000 invoice every 30 days on 45-day terms; *Set up in my books* adds it as an owner-only, undoable Tier-2 operation.
4. **Customers.** Foshan's page shows its worth, financing, payments, deals and exposure, and opens Cash & funding with Foshan 30 days late.
5. **Deals and negotiation** (Figure 1). *Check against my limits* gives the verdict of journey step 3; *Review and send the counter* sends Option A. In the Demo shell, *Open to a counter* agrees in round 1 and *Holds firm* ends in no deal within three rounds with the gap still funded. In Business mode the owner copies FLOW's exact message, marks it as sent and records the answer.
6. **Money and approvals** (Figure 12). Cash & funding runs the Tier-1 legs at once and queues anything above the 15% threshold; Approvals shows each card with its stored quote, and nothing runs until the owner approves (journey step 7).
7. **Time passing.** The Demo's clock replays journey steps 5 to 8; Receivables offers a chase message and *Record a payment*; Activity's *Reconciliation* tab matches each receipt. FLOW warns 7 days before an agreement expires and 14 days before the signed limits do.
8. **Ask FLOW** (Figure 11). "Are we safe?" gets an answer card; 我们安全吗？ is answered in Chinese; "fund the cash gap" proposes a plan that *Yes, run it* runs exactly; a queued request is approved by "approve APR-000001", or by "approve it" right after it was shown; "sign a personal guarantee" is refused for everyone. Appendix G has the rest.
9. **What-if and strategy.** *Try other terms* at 45 days instead of 60 turns the verdict into a counter; nothing is written.

10. **Capex** (Figure 13). *Test a machine without a contract* screens the ¥600,000 machine (section 03, algorithm 8); *Apply* queues a Tier-2 application; *Read the demo vendor contract* and *Commit, paying early* wait on Approvals.
11. **Records, evidence and security.** Activity seals each operation to the one before it; *Download JSONL* exports the record for `scripts/verify_evidence.py`; *Run the FastCapital scene* sends a hostile "pre-approved lender" message: the flagged words are shown, nothing is booked and the harm scoreboard stays at zero.

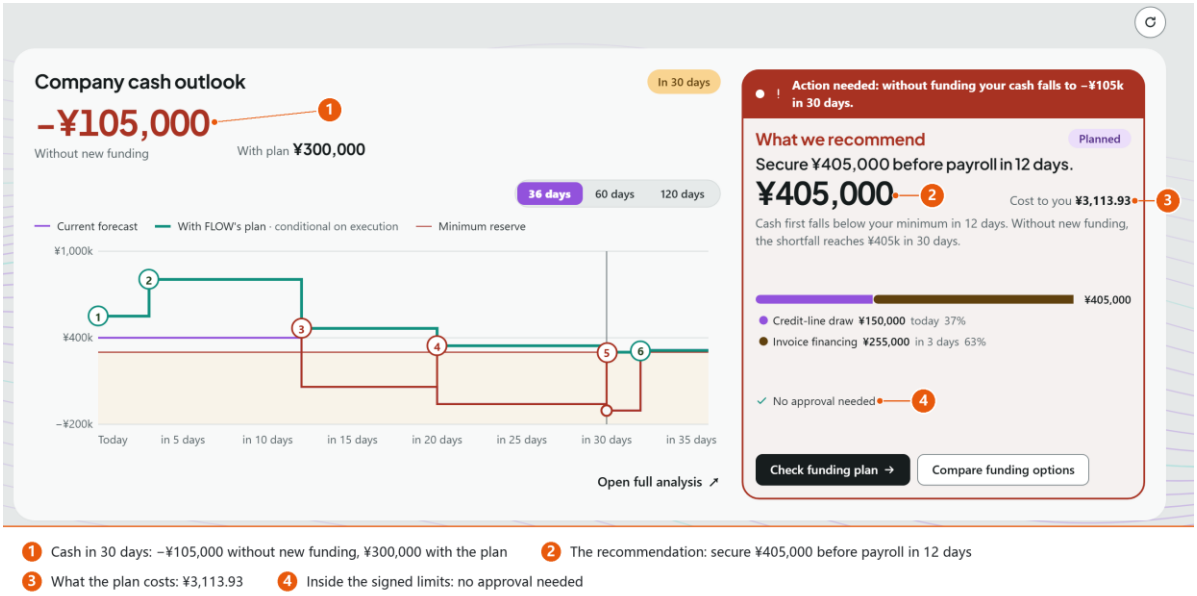

Figure 9. Home on the demo company, day 0: without new funding cash falls to −¥105,000 within 30 days; FLOW recommends securing ¥405,000 before payroll in 12 days, for ¥3,113.93, with no approval needed.

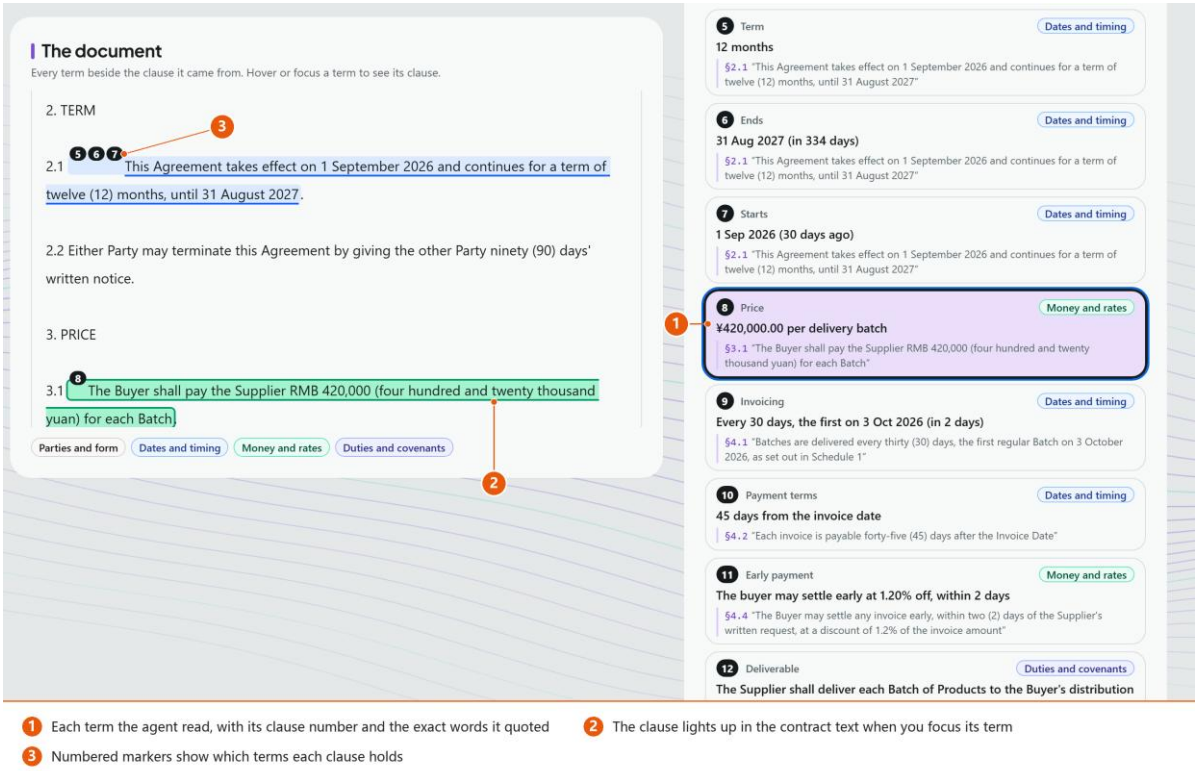

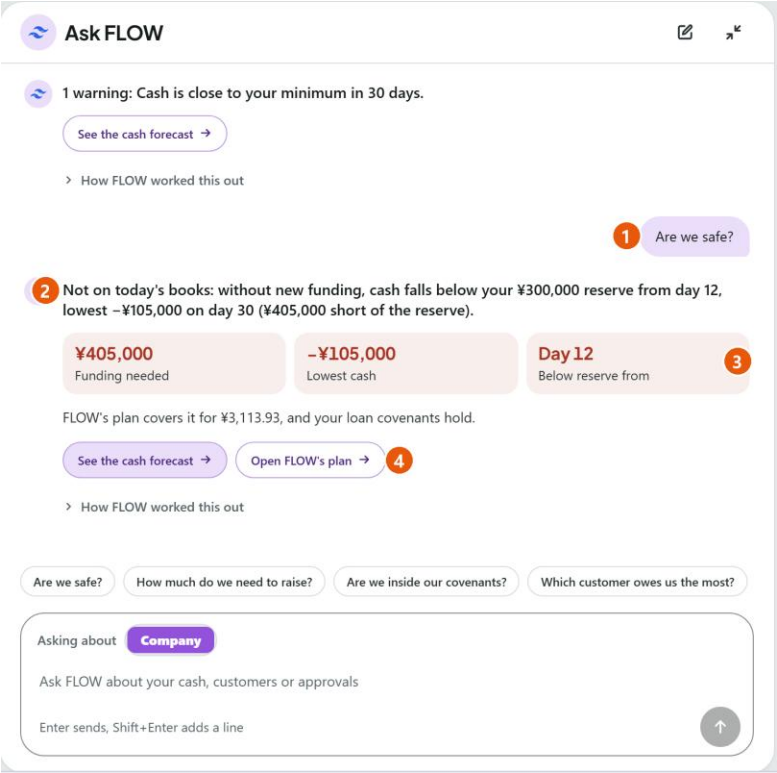

Figure 10. Attach deals: the reading of supply agreement FHR-2026-07. (1) Each term with its clause number and the exact words quoted. (2) The clause lights up when its term is focused. (3) Markers show which terms each clause holds.

1. The owner's question.
2. The answer leads, worked out from the books by code.
3. Three key figures, each a server value.
4. Links to the forecast and the plan; nothing is acted on.

Mock mode, golden books (synthetic), docs/techdoc-chat-fixes @ 571ea64f, captured 18 Oct 2026 at 1440×900

Figure 11. Ask FLOW, day 0 (web app on recorded mocks): "Are we safe?" The card leads with the answer, shows three key figures (¥405,000 funding needed, −¥105,000 lowest cash, below the reserve from day 12), says what FLOW's plan costs, and links to the forecast and the plan. The answer reads; it never acts.

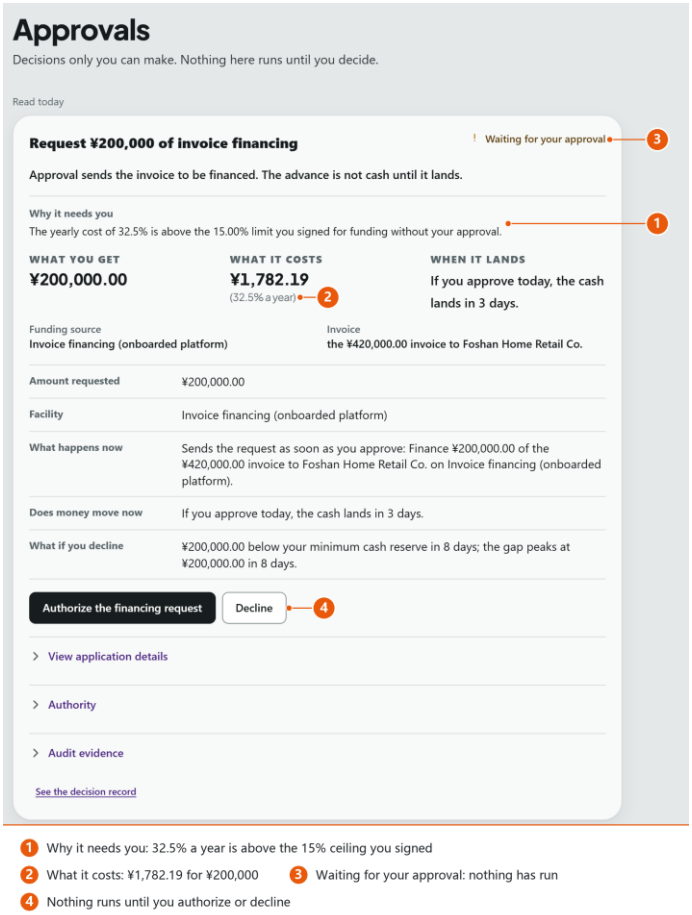

Figure 12. The owner decides what is outside FLOW's limits. On day 34 FLOW proposes a ¥200,000 advance; because it costs 32.5% a year, above the 15% approval threshold, it waits on the Approvals page and nothing has run.

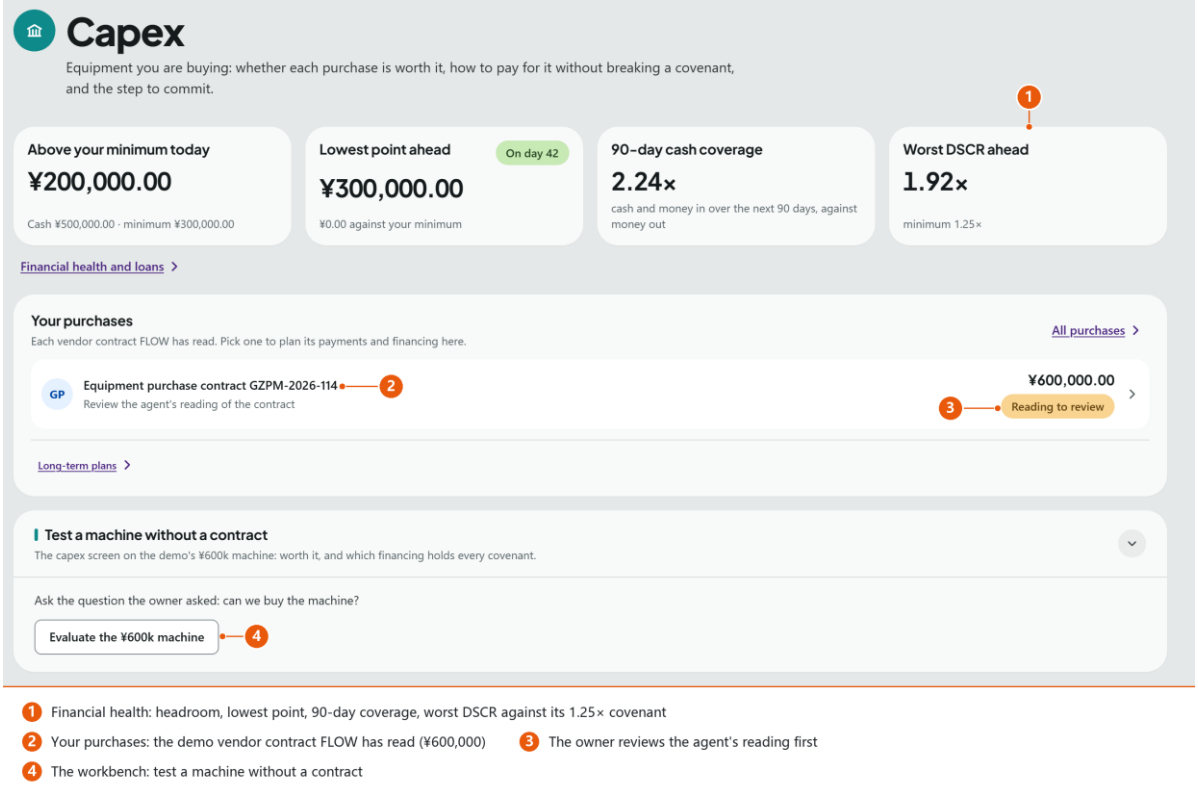

Figure 13. The Capex hub: (1) the financial health figures; (2) the demo vendor contract FLOW has read; (3) the owner reviews the reading first; (4) the workbench to test a machine without a contract.

Appendix L. Products in the same space

Table L1. Products in the same space (vendor descriptions; "difference" is our reading of public material).

Product	What it does	How FLOW differs
Pactum	Buyer-side agents that negotiate payment days, discounts and rebates	FLOW sits on the other side of the table
MYbank 百灵 / AI 票据管家	Lender agents that tailor the bank's own credit and bill products	FLOW is supplier-owned and compares several sources, starting from the trade terms that cause the need
Xero JAX Cash Flow Actions	Ledger-side cash-gap detection and suggested plans	FLOW reads incoming offers and decides them inside a signed mandate and covenants
Cerebro Capital, Capitalise, Codat, Lendio	Lender marketplaces and debt-capacity tools for banks or mid-market firms	FLOW starts before the owner decides to borrow, at the request that creates the need

Appendix M. Terms and codes

Term	Meaning
fen, bp	¥0.01; 0.01%. Money is integer fen and rates integer basis points
Mandate	The owner's signed limits: cash reserve, concession caps, covenant thresholds, the rate and commitment approval thresholds
Reserve (floor)	The lowest closing cash the mandate allows on any day: ¥300,000 on the demo company
Tier 1, 2, 3	What FLOW may do alone inside the mandate; what waits for the owner's approval; what is refused for everyone (Figure 6)

Term	Meaning
Hard rule	A rule no approval can waive: the concession caps, the covenants, a reserve breach no committed funding can cure, an invalid mandate, Tier 3
Approval threshold	A limit above which the owner must approve: a commitment's future concessions above ¥100,000, or funding the agent requests above 15% a year
Golden books	The synthetic demo company, with expected values from an independent oracle
Marginal cost of funds	The all-in rate of the cheapest committed source able to carry a permanent need: 10.84%
Break-even discount	The largest early-payment discount cheaper than that source: 0.8832% for 30 days
Future concession	A promise that costs money later (longer terms, a rebate, a price change), valued at the marginal cost of funds
Coverage proof	The compiler's check that every figure and request in a message is accounted for (ADR-0005)
Tamper-evident	Any edit to the log breaks its hash chain and is detected; it does not stop a database administrator rewriting the whole chain
Cache mode, live mode	Offline reading with the rules grammar and its recorded readings; live calls to a model provider (`--live-llm`)
ADR-nnnn	An architecture decision record (`docs/adr/`)
SEC-nn, R-nn, PRIV-n, REG-n, CT-n	A security finding, risk, privacy item, registry finding or contract set-up finding in the Security Self-Assessment and the findings register
